

# **C+ 158 micron (1.9THz) line as Astronomy tool**

**T. Velusamy**

**Jet Propulsion Laboratory,  
California Institute of Technology**

**Colloquium at NCRA (GMRT), Pune, India**

**July 23, 2012**

# Outline

- The “cool” Infrared Universe
- Carbon and C<sup>+</sup> line emissions tracing the ISM gases
  - C<sup>+</sup> as diagnostic tool for “H<sub>2</sub> Dark gas”
- GOT C<sup>+</sup> survey of Galactic Plane: demonstrate the utility of CII
  - Transition Clouds
  - WIM in Spiral tangencies
  - CRRL and C<sup>+</sup> in a “local” HI self absorption cloud
- **C<sup>+</sup> for external galaxies**
- **Summary**

# The Universe is Cool!!

About 50% of the energy created since the formation of the Cosmic Microwave Background (CMB) has been reprocessed into the infrared!!

Most of the universe's photons are in the InfraRed (IR)!!  
Infrared Radiation is Recycled Starlight from Dust and Gas

# Dust Extinction – Blocks Out Starlight

Dust scatters and absorbs visible & UV efficiently

(red less than blue less than UV)

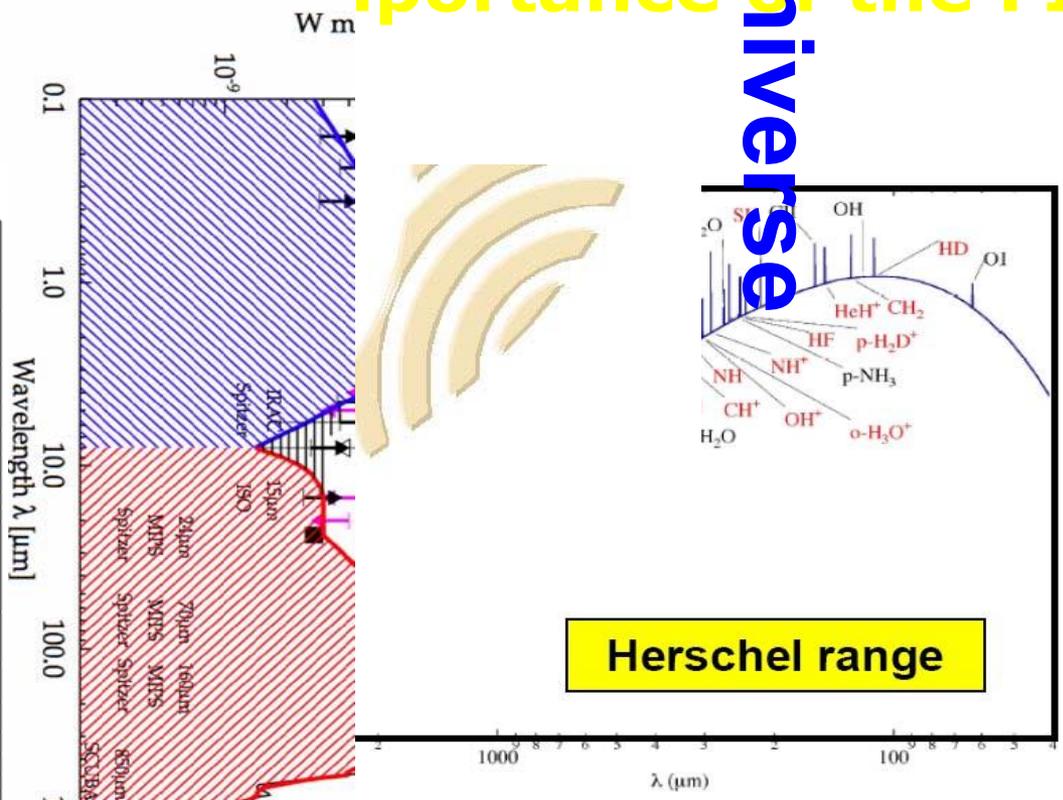

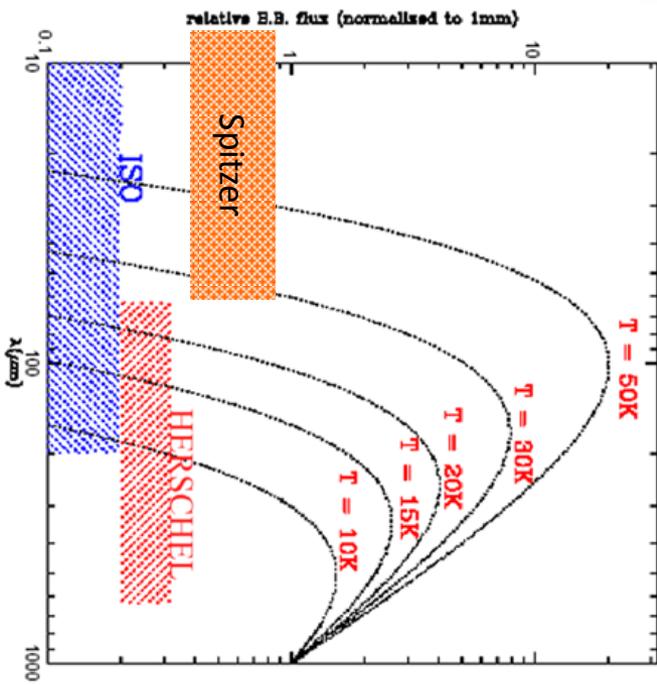

Dust does not absorb infrared efficiently

Absorbed radiation heats dust and gas

UV ionizes atoms and photodissociates (breaks up) molecules

# Importance of the FIR

Dust & gas cool by

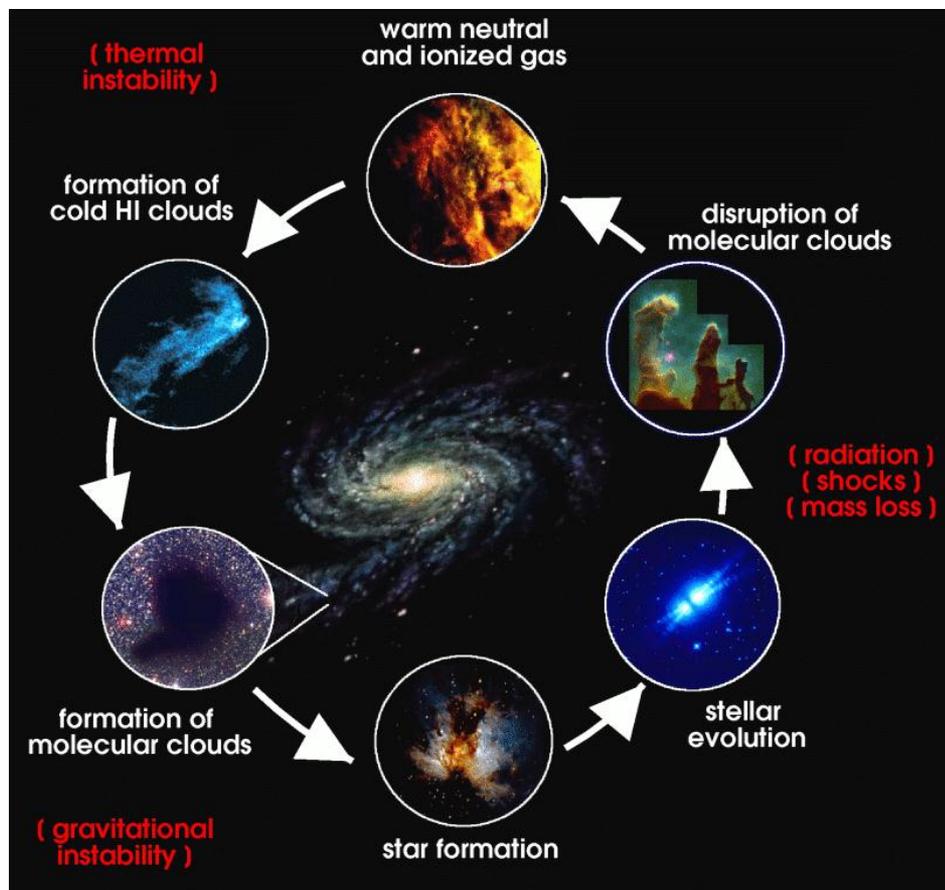

Dust radiates over a continuum of wavelengths (black body radiation)

half of the energy created in the CMB has been reprocessed by dust. Every atom, ion, and molecule has distinct spectral signatures

SPLÉ, Marseille 23 Jun 2008  
Göran L. Pilbratt VG #7  
<http://herschel.esac.esa.int/>

# Gas to Stars to Gas to Stars to Gas ....

Most abundant molecules  
H<sub>2</sub> molecular hydrogen  
CO – carbon monoxide

Stars form out of  
interstellar gas clouds

Stars produce heavy  
elements: C, N, O, Fe, ...  
(we are stardust)

Stars eject gas back and  
disrupt clouds

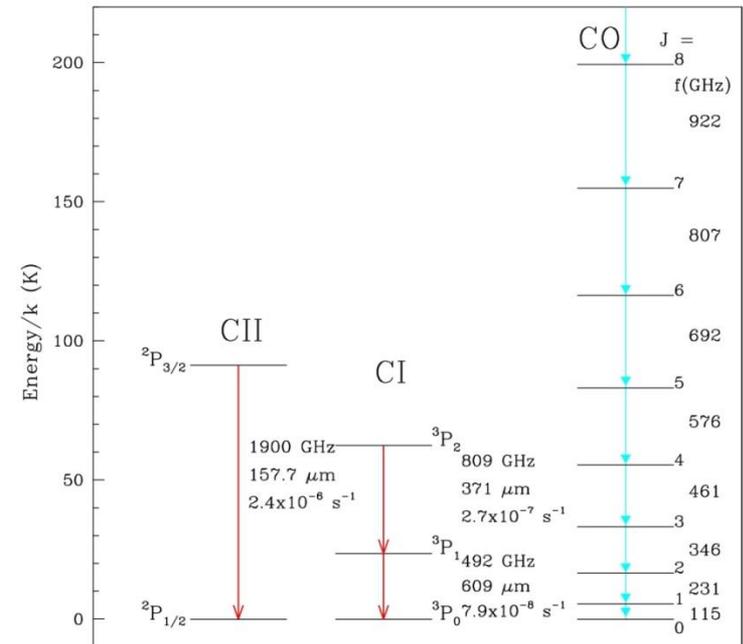

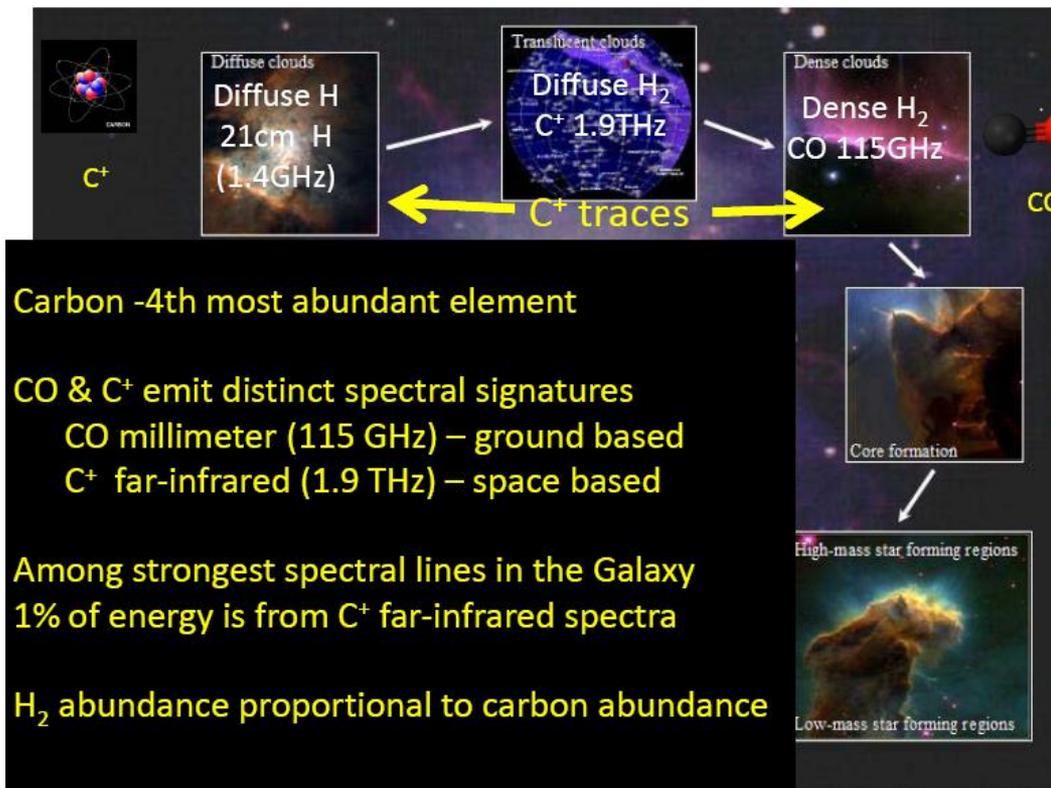

Elemental Abundances

- 91% Hydrogen + 9% Helium
- 0.1% Oxygen, Carbon, Nitrogen,
- 0.01% Everything else: Silicon, Iron, etc

# WHY CARBON SPECIES

*“So it happens, therefore, that every element says something to someone (something different to each) ..... One must perhaps make an exception for carbon, because it says everything to everyone ... .*

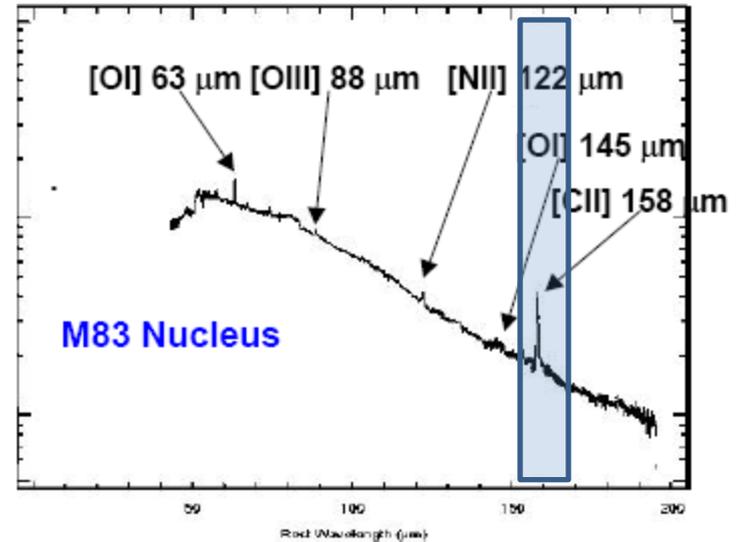

*-- Primo Levi, chemist and author, in The Periodic Table, Chapter 21 on Carbon (1975).*

Important as star-formation rate in galaxies → galaxy evolution

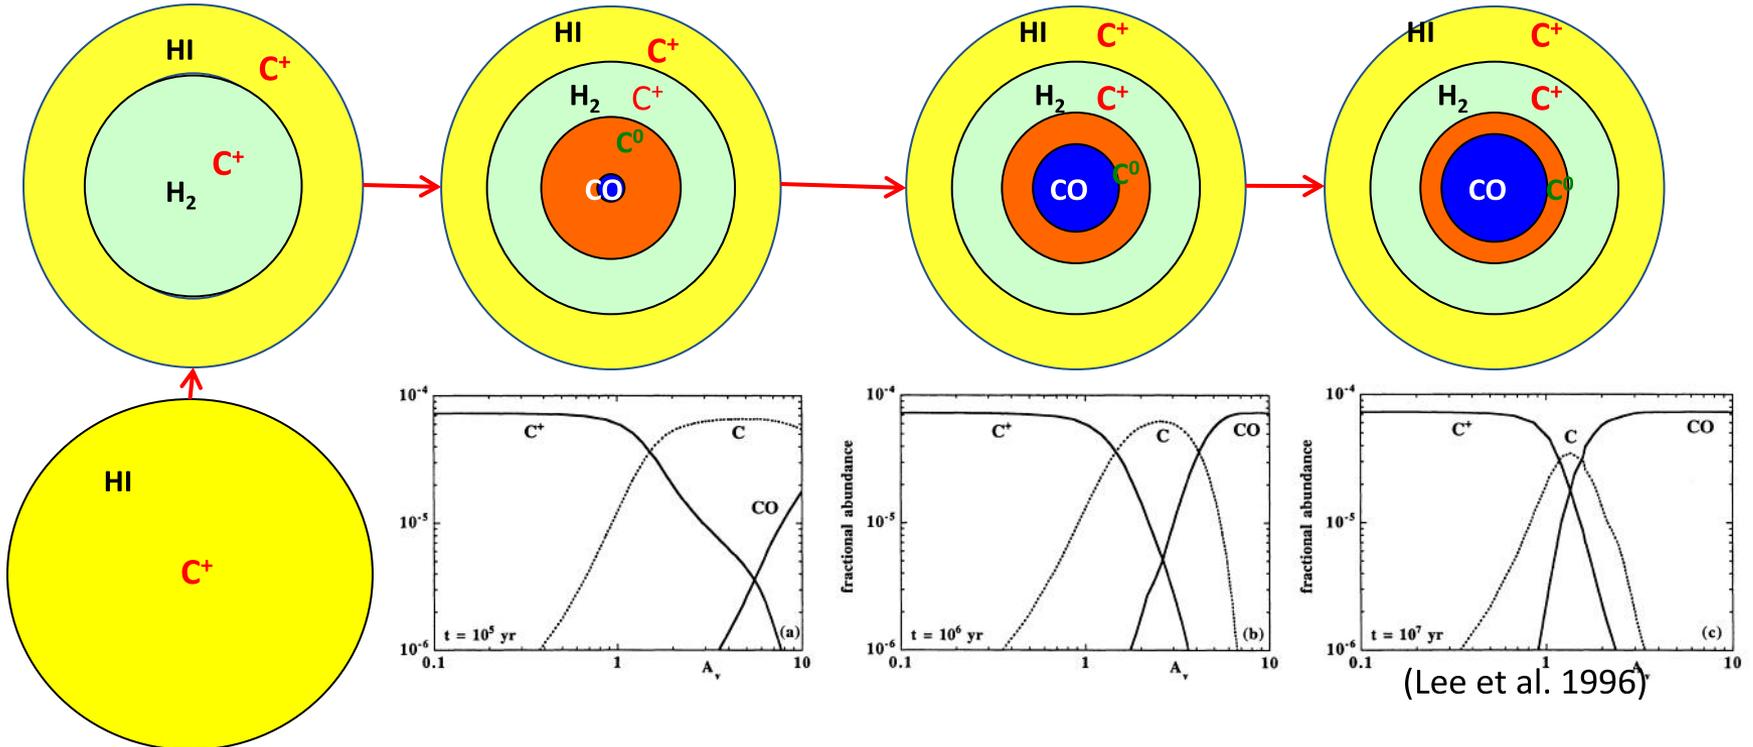

# WHY C<sup>+</sup> 158 micron line

- C<sup>+</sup> is ubiquitous. Atomic carbon exists mostly ionized (C<sup>+</sup>), except in a thin layer in PDRs as neutral (C<sup>0</sup>)
- C<sup>+</sup> 158um is the brightest submm spectral line
- A robust tracer of total interstellar gas
  - Emitted under a wide range of interstellar environments: From fully ionized to cold dense clouds, excited by collisions with
    - electrons, (in warm ionized medium: WIM),
    - atomic hydrogen (in Warm Neutral Medium: WNM)
    - molecular hydrogen (in Cold Neutral Medium:
- Tracer of star-formation
  - Galaxy evolution throughout the universe: nearest to highest redshift galaxies
- New opportunities
  - Access from space: Herschel, SOFIA
  - THz Heterodyne technology provide spectrally resolved C<sup>+</sup> line data (HIFI on Herschel and GREAT on SOFIA)

Collider	Temperature (K)	$n_{cr}$ ( $cm^{-3}$ )
e <sup>-</sup>	500	15
	10000	48
H <sup>0</sup>	20	3800
	100	3000
	1000	2100
	8000	1200
H <sub>2</sub>	20	7700
	100	6100
	500	4800

# [CII] Tracks Interstellar Cloud Evolution

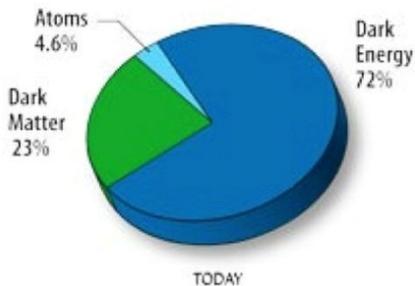

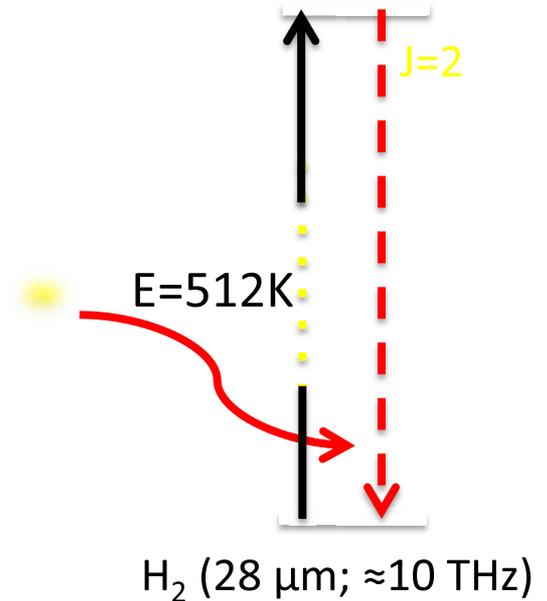

- Diffuse Atomic Clouds
  - HI traces  $N(H)$
  - [CII] traces warm, dense H
- Diffuse Molecular Clouds
  - [CII] traces warm HI & H<sub>2</sub>
  - No CO

- Transition Clouds
  - H<sub>2</sub> & C<sup>+</sup>,
  - C<sup>0</sup> & CO
  - [CII] → warm, dense H<sub>2</sub>
- Dense Molecular Clouds
  - <sup>12</sup>CO & <sup>13</sup>CO

# “H<sub>2</sub> Dark Gas”: How much H<sub>2</sub> gas is missed?

- In cold, star-forming environments H<sub>2</sub> is not detected directly, but inferred from other molecular lines observed, usually CO.
- CO line intensities are used to infer the amount of H<sub>2</sub>
- Presence a significant amount H<sub>2</sub> in the Galactic ISM, which is not traced by CO emission was evident from:
  - Star forming cloud models show H<sub>2</sub> layer without CO (Wolfire et al. 2010, ApJ 716, 1191)
  - Dust emissions (Reach et al. 1994, ApJ 429, 672)
  - Gamma ray observations (Abdo, et al. 2010, ApJ 710, 133)
- Recent Herschel HIFI C<sup>+</sup> 158μm line survey (GOT C+) detected this “H<sub>2</sub> Dark Gas” component by the C<sup>+</sup> emission from the H<sub>2</sub> layers without CO, thus missed by CO data. (Velusamy, Langer et al. 2010, A&A 521, L18), & Langer, Velusamy et al. 2010, A&A 521, L17)

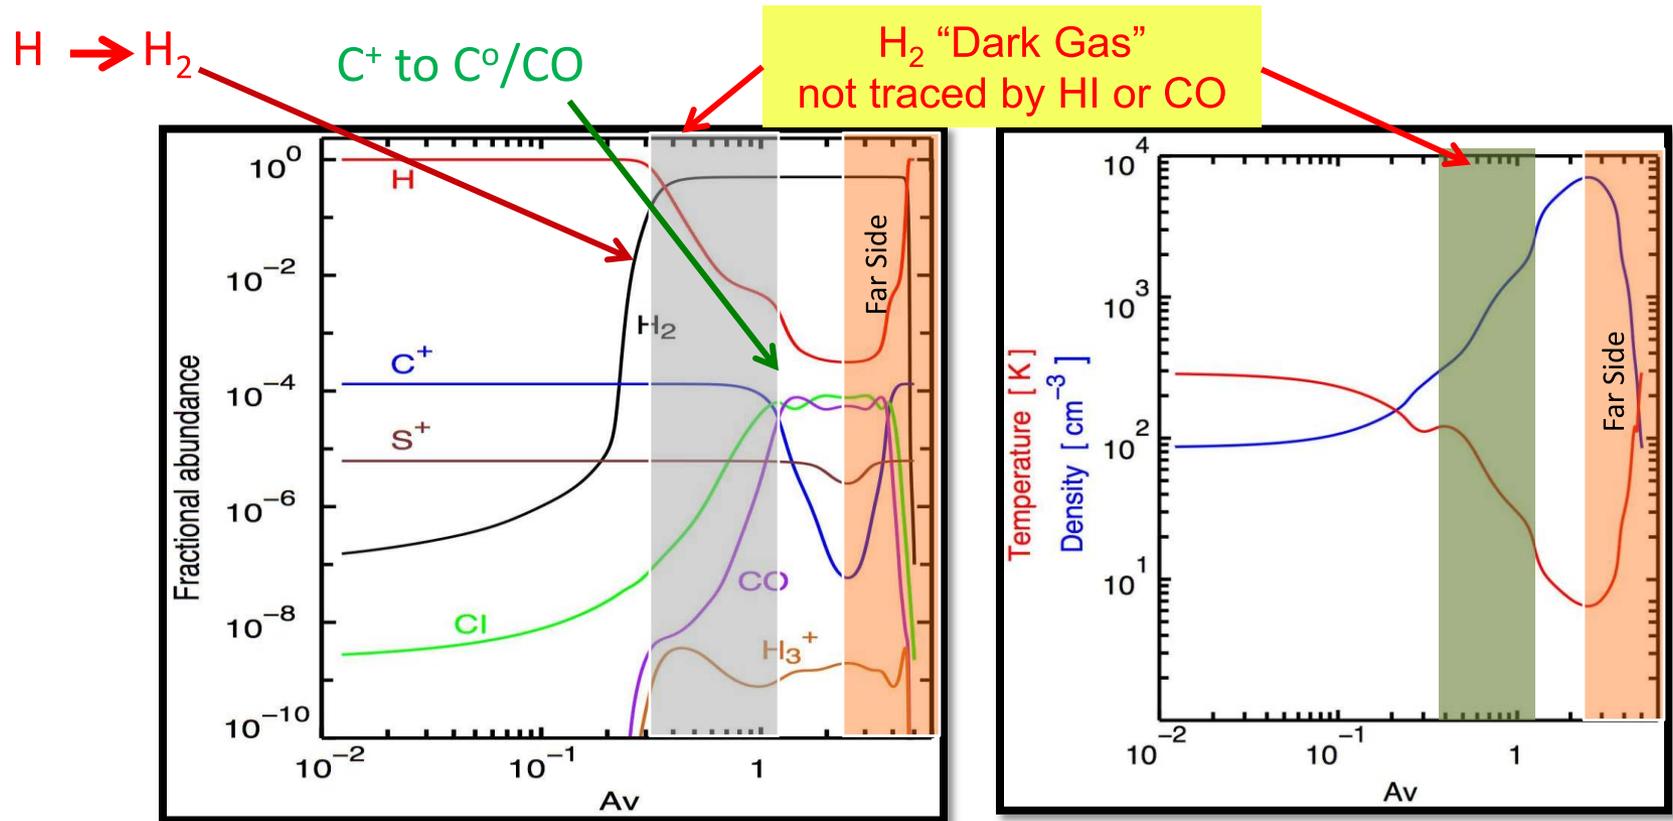

Lowest Molecular Hydrogen line

**“Dark Gas” is NOT “Dark Matter”.** It is ordinary molecular hydrogen, H<sub>2</sub>, in regions where it is too cold to radiate and so is “Dark”

Caution: This is something else!

# Transition Cloud Model of HI and [CII]

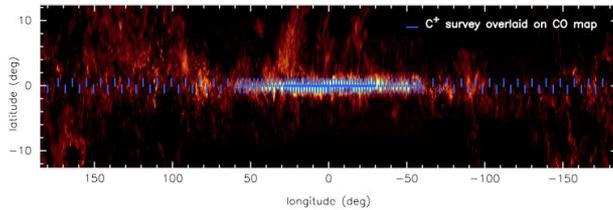

- $l_0 \sim 50$  (finite slab - both sides illuminated) &  $P \sim 2 \times 10^4 \text{ K cm}^{-3}$
- $n(\text{HI}) \sim 50 - 100 \text{ cm}^{-3}$ ,  $T_{\text{kin}} \sim 100 \text{ to } 200 \text{ K}$
- $n(\text{H}_2, \text{CII}) \sim 2-8 \times 10^2 \text{ cm}^{-3}$  &  $T_{\text{kin}} \sim 50 - 100 \text{ K}$

# GOT C+ [CII] 1.9 THz Survey

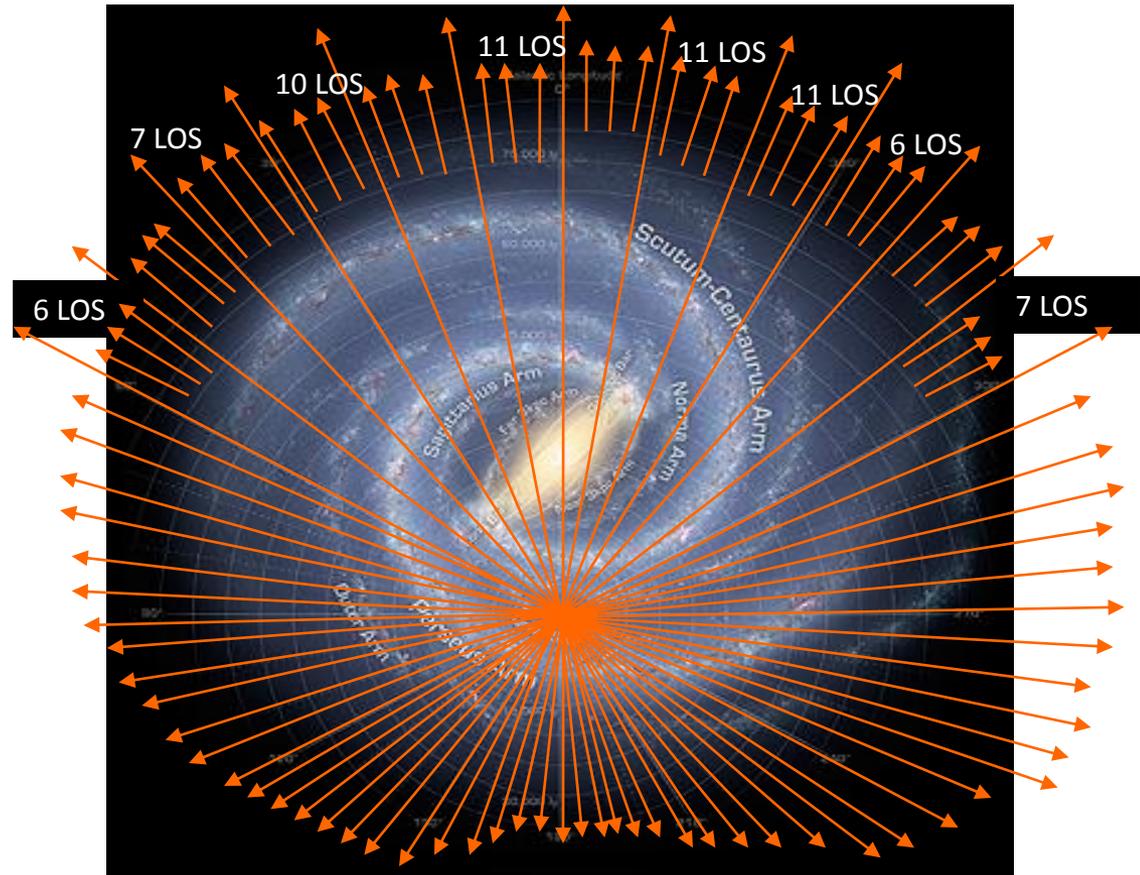

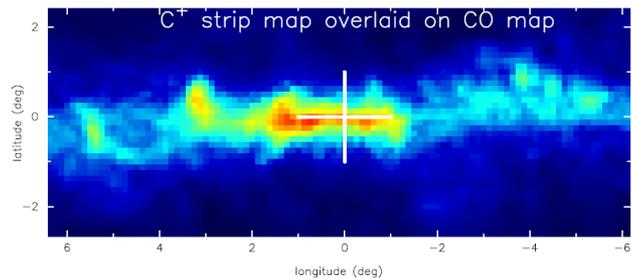

A OT Key project (PI: Langer)

Galactic Plane Survey - systematic volume weighted sample of  $\approx 500$  LOSs in the disk

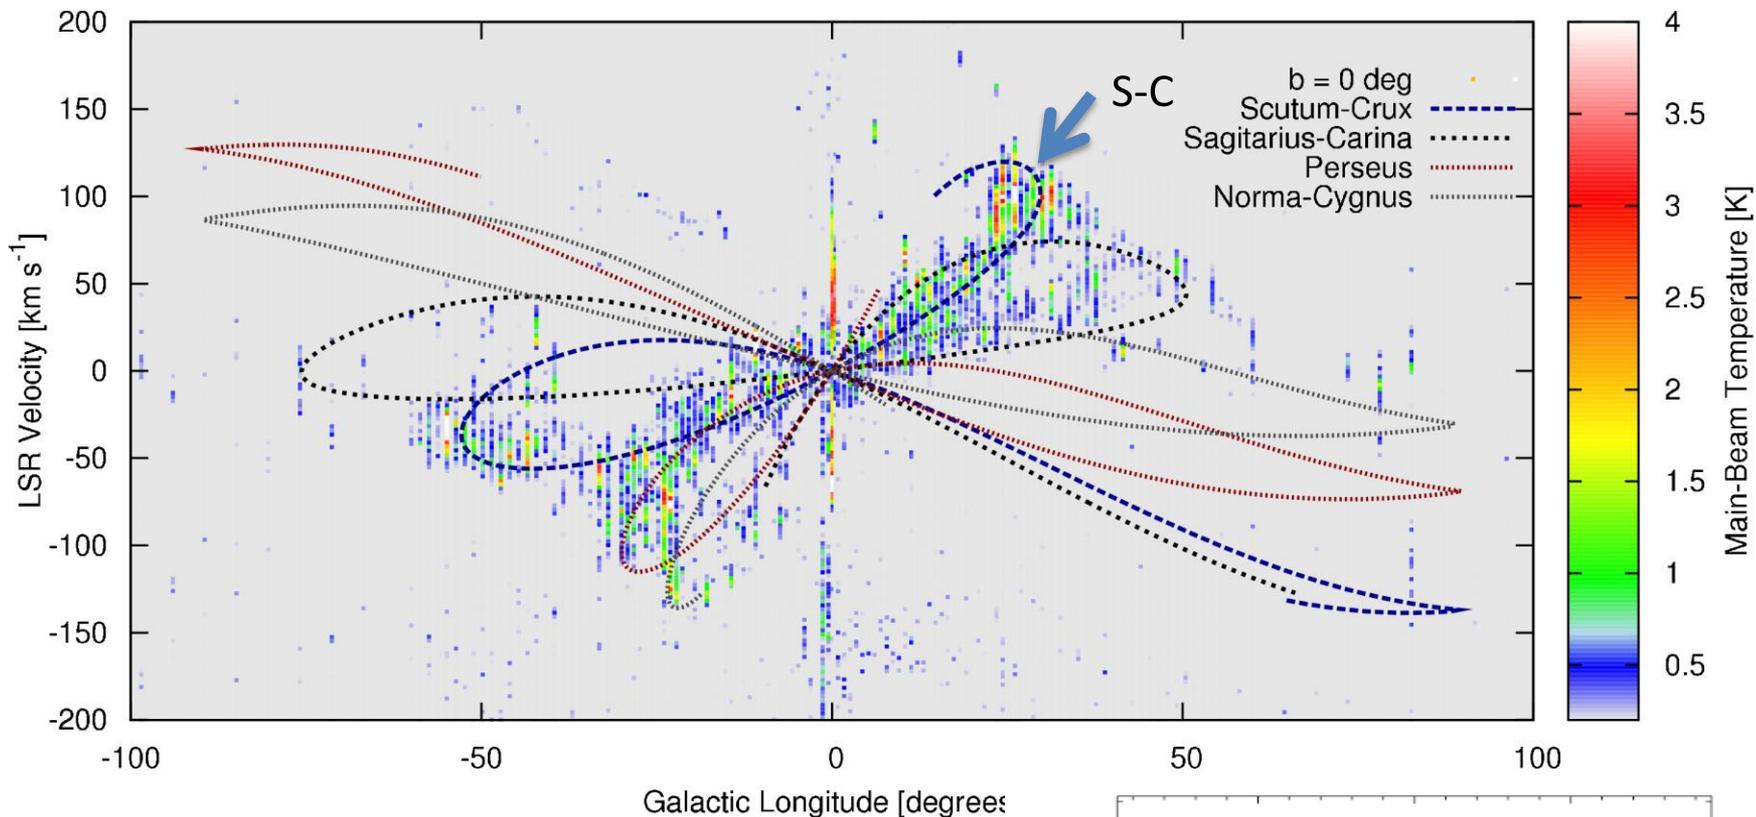

- Concentrated towards inner Galaxy
- Sampled  $l$  at  $b = 0^\circ$ ,  $\pm 0.5^\circ$  &  $1^\circ$

Galactic Central Region: CII strip maps sampling  $\approx 300$  positions in On The Fly (OTF) mapping mode.

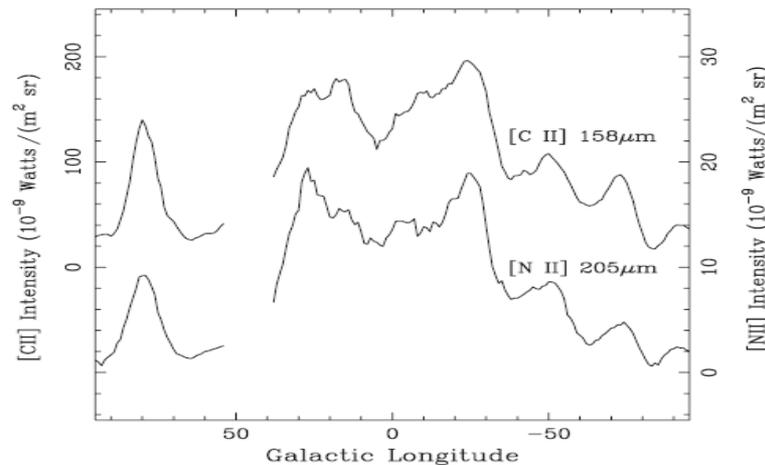

# [CII] Distribution in the Milky Way: GOTC+ (*l-v*) map

GOT C+ Spectrally resolved [CII] Galactic Plane Survey:  
 Global Distribution of ISM Gas - Pineda et al. (2012) in  
 preparation.

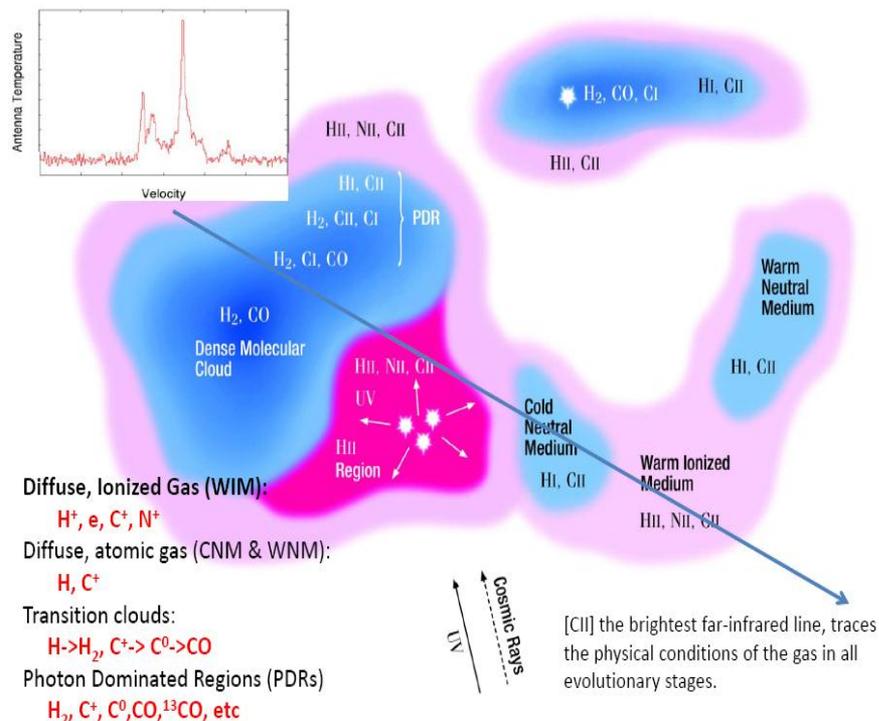

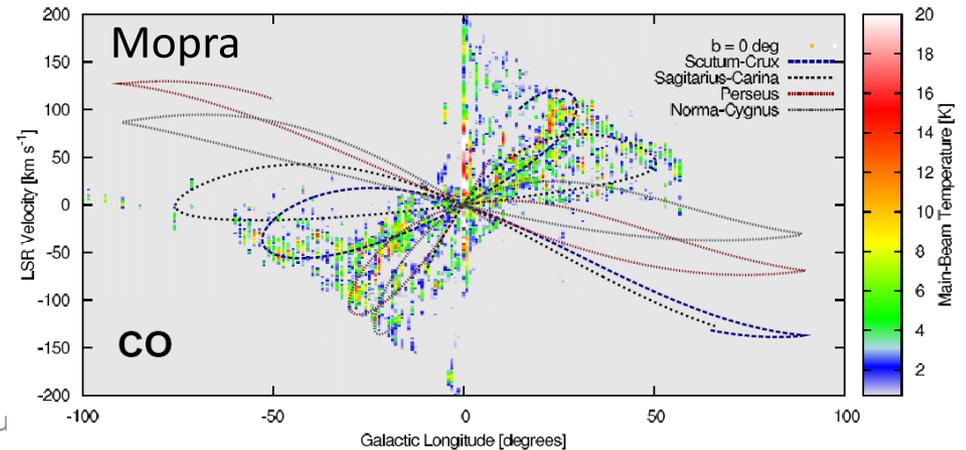

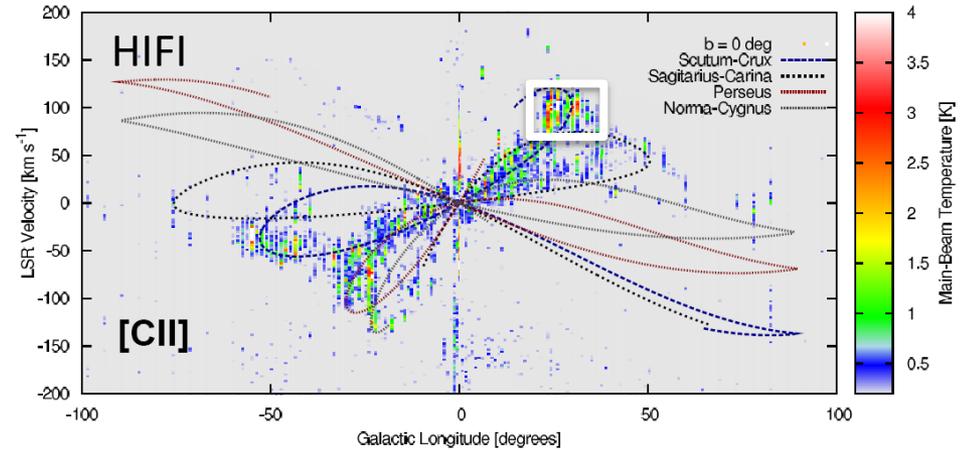

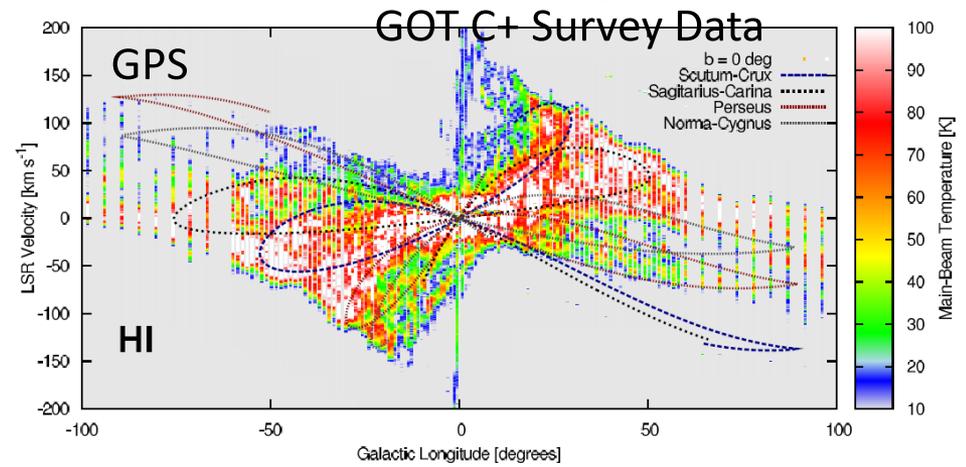

COBE data (Stieman-cameron et al. 2010)

# Interstellar Medium (ISM) components:

## Spectra based extraction

## Using GOT C+ Survey Data

Diffuse, Ionized Gas (WIM):

H<sup>+</sup>, e<sup>-</sup>, C<sup>+</sup>, N<sup>+</sup>

Diffuse, atomic gas (CNM & WNM):

H, C<sup>+</sup>

Transition clouds:

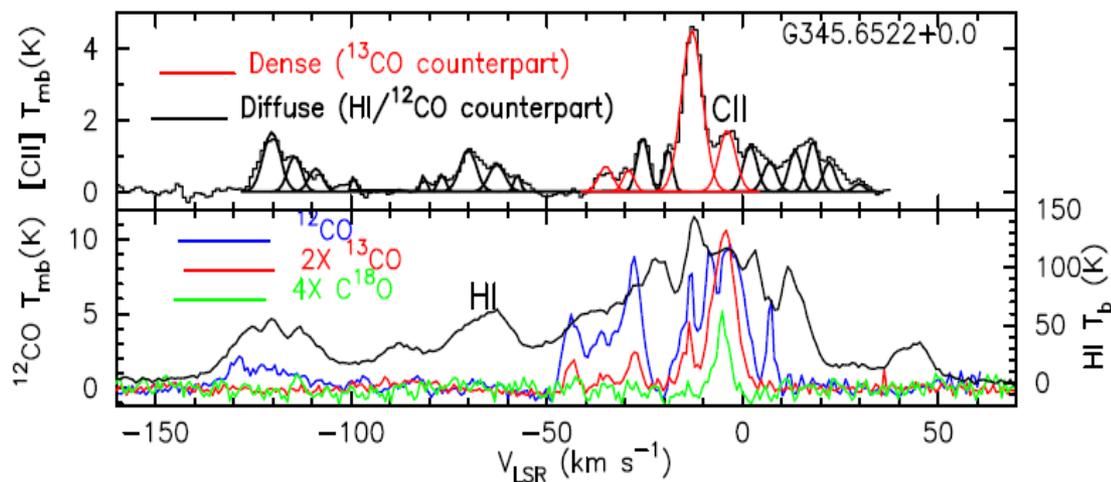

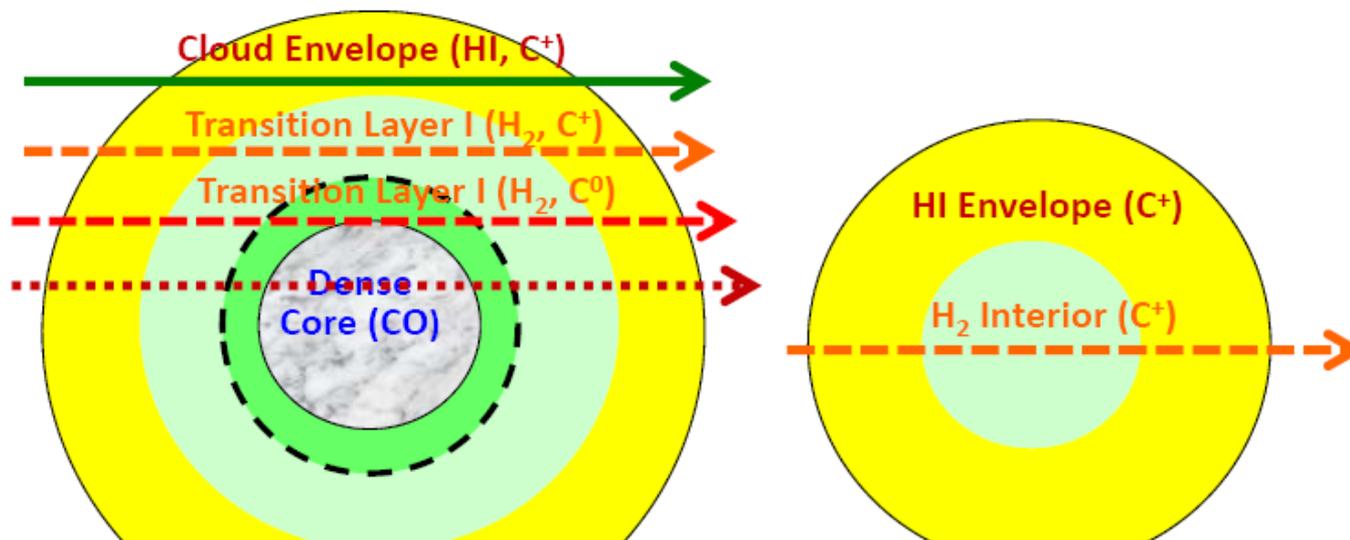

H<sub>2</sub> → H<sub>2</sub><sup>+</sup>, C<sup>+</sup> → C<sup>0</sup> → CO

Photon Dominated Regions (PDRs)

H<sub>2</sub>, C<sup>+</sup>, C<sup>0</sup>, CO, <sup>13</sup>CO, etc

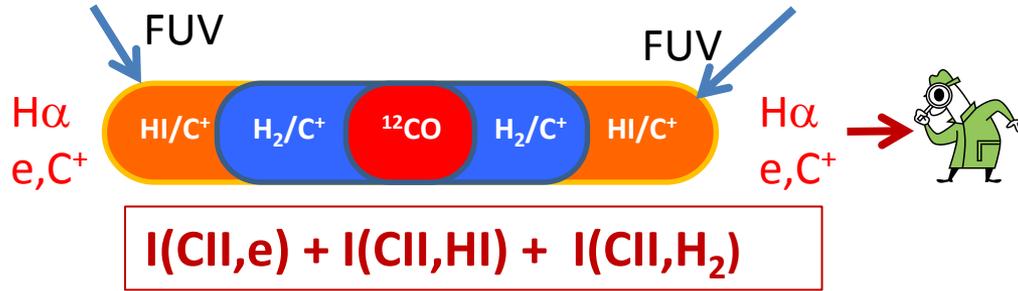

# Statistical analysis of transition clouds -2

What is observed by single LOS?

Models estimate about 30% H<sub>2</sub> gas in the transition layers which is not traced by CO (Wolfire et al. 2010)

# Statistical analysis of transition clouds -3

$I(\text{CII}) \rightarrow N(\text{HI}) + N(\text{H}_2)$  up to  $\text{C}^+/\text{C}^0/\text{CO}$  transition

Clouds selected by  $[\text{CII}] + ^{12}\text{CO}$ , but no  $^{13}\text{CO}$  emissions

$N(\text{HI}) \propto I(\text{HI})$

$$I(\text{CII})_{\text{HI}} = f(n_{\text{HI}}, T_K) N(\text{HI}) x(\text{C}^+)$$

( $f$  = excitation of  $\text{C}^+$ )

$[\text{CII}]$  sensitive to  $(n, T)$  or  $P$

$$I(\text{CII})_{\text{H}_2} = I(\text{CII}) - I(\text{CII})_{\text{HI}}$$

where  $I(\text{CII})_{\text{H}_2}$  indicates the CII emission from the  $\text{H}_2$  layer

$$N(\text{C}^+)_{\text{H}_2} = f(n_{\text{H}_2}, T_K)^{-1} I(\text{CII})_{\text{H}_2}$$

$$N(\text{H}_2)_{\text{C}^+} = N(\text{C}^+)_{\text{H}_2} / x(\text{C}^+)_{\text{H}_2}$$

Langer, (2010, 2011) & Velusamy, et al. (2010, 2011)

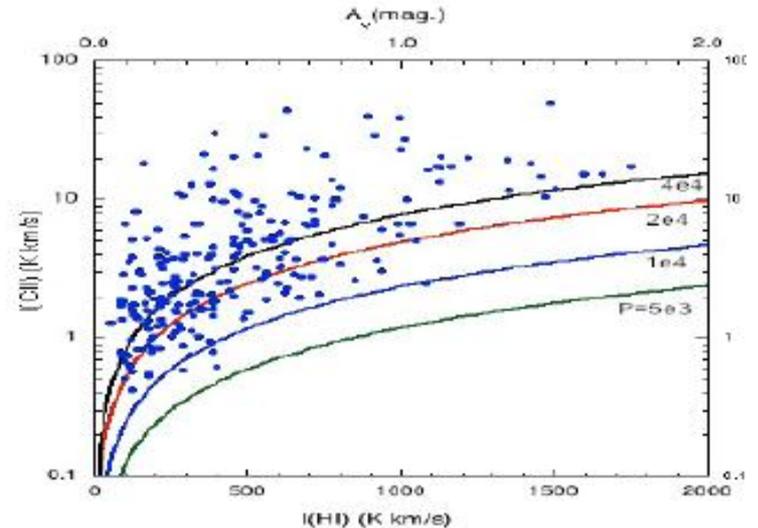

Fig. 4  $[\text{CII}]$  versus HI intensities

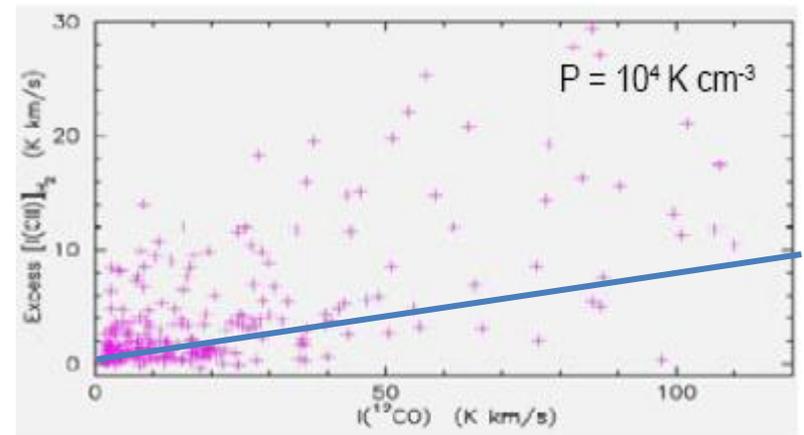

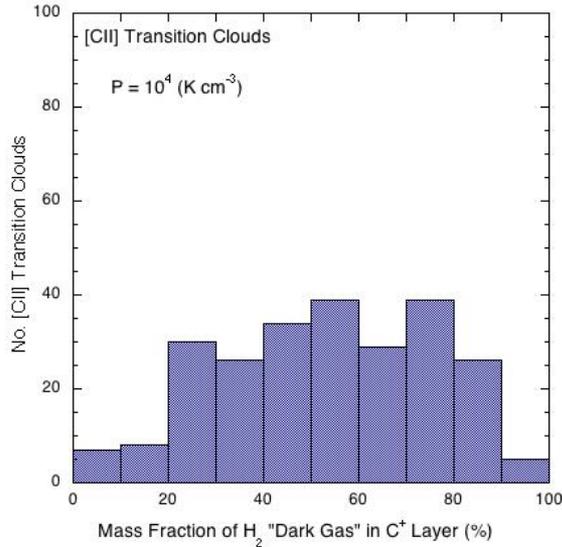

Fig. 6 Excess  $[\text{CII}]$  versus  $^{12}\text{CO}$  intensities

# “Dark H<sub>2</sub> Gas” Mass Fraction

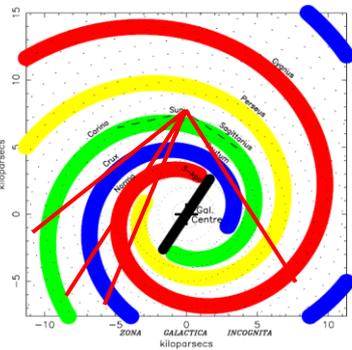

- Use excess I(CII) to estimate  $N(\text{H}_2)_{\text{CII}}$ 
  - $I(\text{CII})_{\text{H}_2} = I(\text{CII})_{\text{tot}} - I(\text{CII})_{\text{HI}}$
- Fractional H<sub>2</sub> mass in the H<sub>2</sub>-C<sup>+</sup> layer of transition clouds

$$f = \frac{M(\text{H}_2)_{\text{CII}}}{M(\text{HI}) + M(\text{H}_2)_{\text{CII}} + M(\text{H}_2)_{\text{CO}}}$$

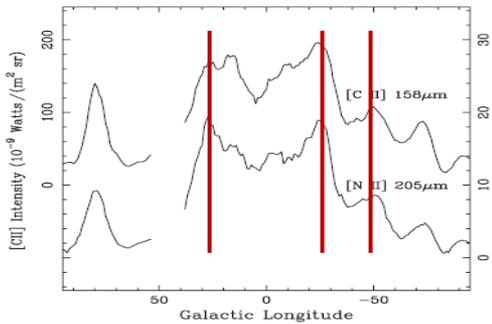

- Higher Pressure corresponds to a narrower distribution
- [CII] diffuse and transition clouds have significant amounts of warm dense H<sub>2</sub> in addition to a warm dense HI layer
- Need more information about the C<sup>0</sup>/CO transition zone from [CI] and high-J CO

We have OT1 (PI: Velusamy) HIFI OTF mapping in [CII]

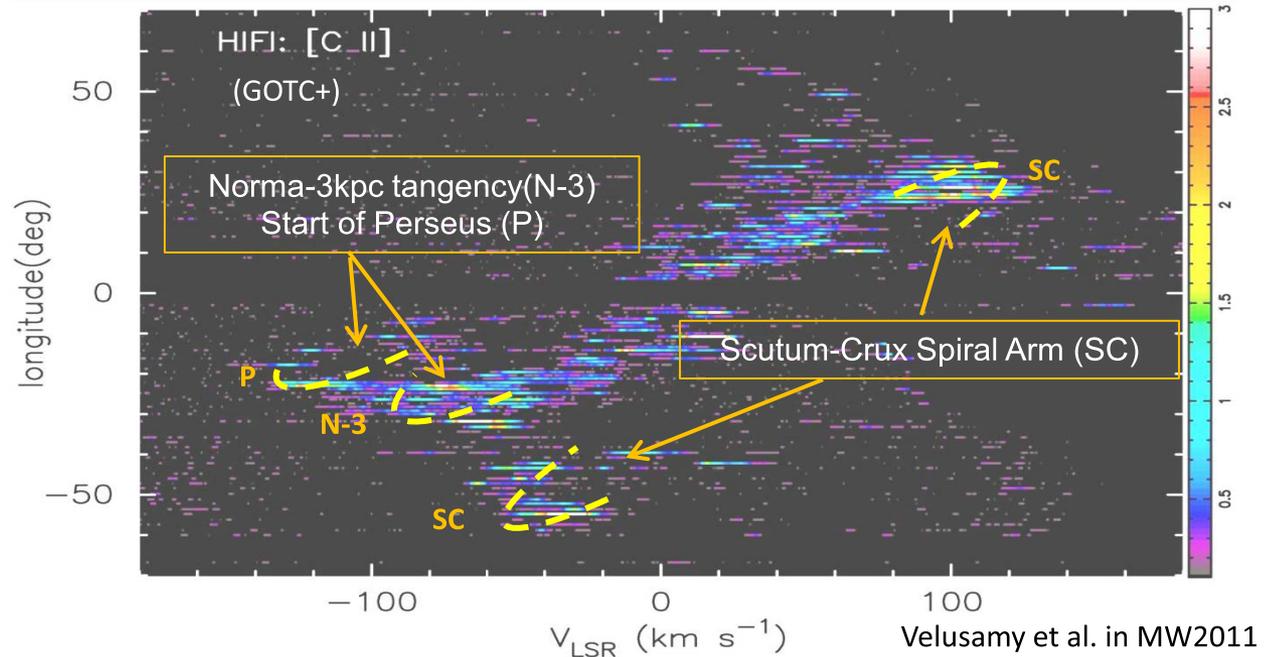

# GOT C+ survey detects strong [CII] in Galactic Spiral arm tangencies

Vallee (2008)

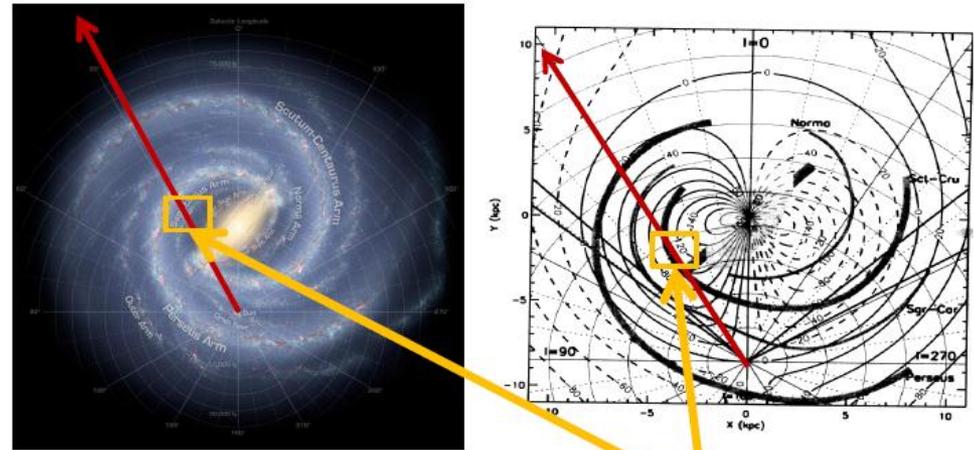

COBE data — Steiman-Cameron et al. (2010)

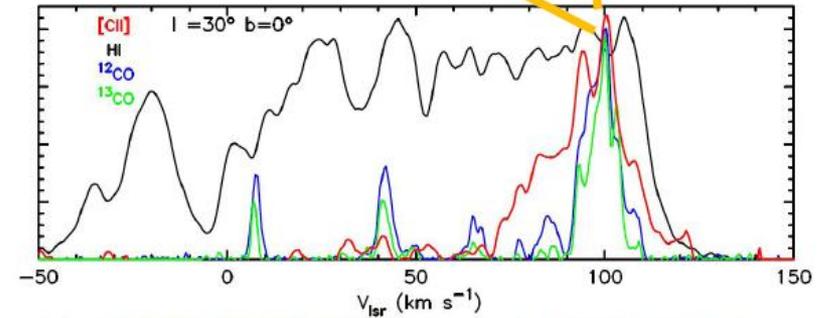

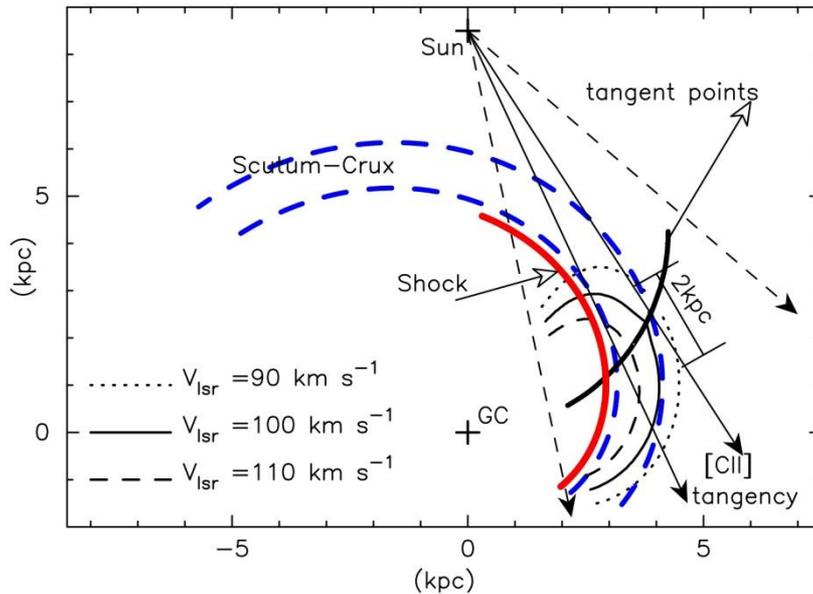

Velusamy et al. in MW2011

# Isolating Different ISM Regions with HI, CO, and [CII] In the Scutum-Crux Tangency

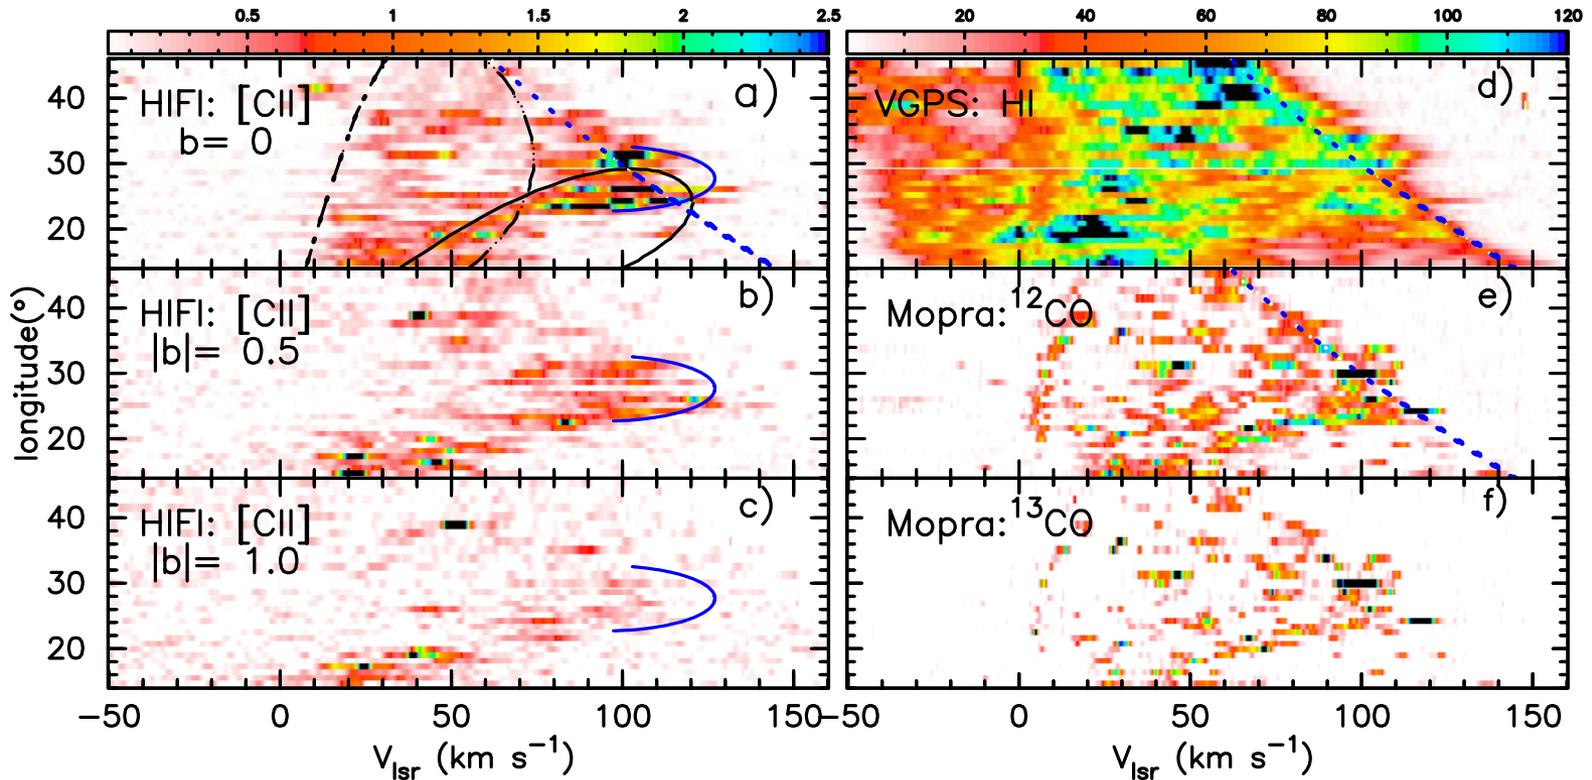

Velusamy, Langer et al. 2012, A&A 541,L10

The geometry of the Scutum-Crux (S-C) arm is very favorable to detect weak CII emission from the WIM and study its structure and kinematics

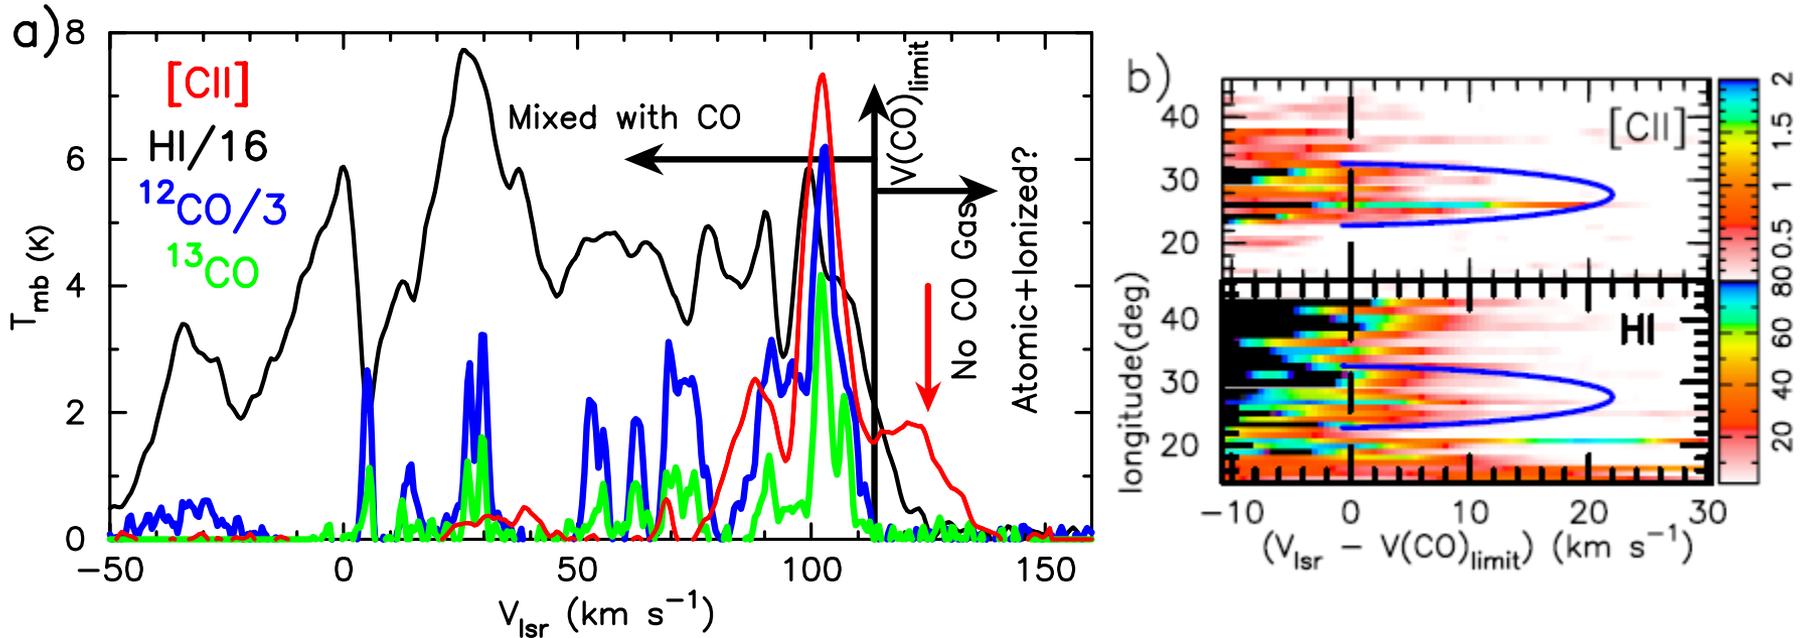

# CII, HI, and CO Isolate WIM in Spiral Tangency

( $l, v$ ) maps of CII, HI, CO near Scutum-Crux tangency. Blue arc = loci of velocities traced by CII. The loci of the spiral arm velocities are: S-C (solid line) and Sagittarius – Carina (dashed). The dashed blue line shows the tangent velocity as a function of longitude.

# CII, HI, and CO in Spiral Tangency -2

[CII] detected along spiral arm tangencies (long path length) with no CO and little HI. [CII] determines the WIM density and electron abundance

Near the S-C tangency CII and HI show emission significantly beyond the tangent velocities and well above  $^{12}\text{CO}$ . Red arrow – bright anomalous CII at  $V >$  tangent velocity (110  $\text{km/s}$ ) associated with weak HI.

The excess emission at high velocities,  $> V(\text{CO})_{limit}$ , is seen at all longitudes for HI, but only in the S-C longitudes for [CII].

# WIM Properties From [CII]

In the optically thin low density limit

$$I(CII) = I_{CNM} + I_{WNM} + I_{WIM}$$

$$I_{WIM}(CII) = a \frac{n(e)}{n_c(e)} N_{WIM}(C^+) e^{-\Delta/T}$$

$$I_{CNM}(CII) = a \frac{n(HI)}{n_c(HI)} N_{CNM}(C^+) e^{-\Delta/T}$$

$$I_{WNM}(CII) = a \frac{n(e, HI)}{n_c(e, HI)} N_{WNM}(C^+) e^{-\Delta/T}$$

Critical Densities

$$n_c(HI) = A_{ul} / \langle \sigma v \rangle_{ul}$$

$$n_c(HI)_{T=100K} \approx 3.2 \times 10^3 \text{ cm}^{-3}$$

$$n_c(HI)_{T=8000K} \approx 1.3 \times 10^3 \text{ cm}^{-3}$$

$$n_c(e)_{T=8000K} = 46 \text{ cm}^{-3}$$

$n(e) / n(HI) > 0.05$  Electrons Dominate

Electron excitation dominates in WIM

# [CII] from CNM HI Clouds?

$$I(\text{CII}) = a \frac{n(\text{H})}{n_c(\text{H})} e^{-\square\square/T} N(\text{C}^+) \text{ Kkm / s}$$

$$N(\text{C}^+) = n(\text{H})x(\text{C}^+)L$$

$$N(\text{H}) = n(\text{H})L \mu I(\text{HI})$$

$$n(\text{H}) \mu \frac{n(\text{H})e^{-\square\square/T} I(\text{CII})}{x(\text{C}^+)I(\text{HI})}$$

$$n(\text{H}; T = 100\text{K}) = 6.3 \square 10^4 \frac{I(\text{CII})}{x_{\square 4}(\text{C}^+)I(\text{HI})} \text{ cm}^{\square 3}$$

$$n(\text{HI}) \square 160 \square 500 \text{ cm}^{\square 3}$$

But Observed  $< 1\text{cm}^{-3}$

→ [CII] is from WIM

# WIM Properties from [CII]

$$I(\text{CII}) = a \frac{n(e)}{n_c(e)} e^{-\square\square/T} N(\text{C}^+) \text{ Kkm / s}$$

$$N(\text{C}^+) = n_t x(\text{C}^+) L \quad n(e) = x(e) n_t$$

$$n_t = 0.32 \left[ \frac{T_3^{0.37} I(\text{CII})}{x_{\square 4}(\text{C}^+) x(e) L_{kpc}} \right]^{0.5} \text{ cm}^{\square 3}$$

$$n_t = 0.27 \left[ \frac{I(\text{CII})}{L_{kpc}} \right]^{0.5} \text{ cm}^{\square 3}$$

# WIM Properties in S-C Arm from [CII]

CII & HI Intensities and Derived Parameters for S-C Tangency

LOS	I(CII)	I(HI)	L(kpc)*	n(e) (=n(H+))	<n(HI)>	f(WIM)	<n(e)> cm(-3)

Avg b=1.0	1.5	672	3.5	0.13	0.11	0.54	0.18

\* Constrained by the highest velocity contours in the ( $l$ - $v$ ) maps

- $\langle n(e) \rangle = 0.45 \text{ cm}^{-3}$  at  $b=0^\circ$ , 3-7 times larger than WIM outside spiral tangencies
- $\langle n(e) \rangle$  decreases with  $b$ , consistent with lower gravitational potential of arms
- Comparison of CNM/WNM HI clouds with WIM  $\rightarrow$  50% - 70% linear filling factor

# WIM in S-C Arm from [CII]

The relatively weak HI emission implies we are detecting WIM and not WNM.

The average densities derived from the [CII] excess are several times higher than the LOS averaged densities inferred from pulsar dispersion and H-alpha measurements.

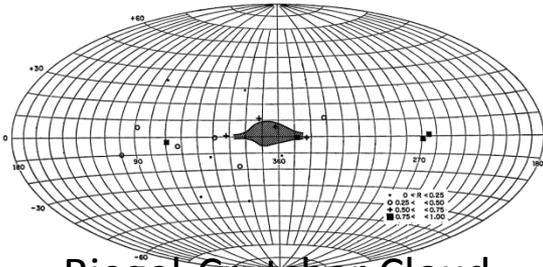

Larger mean densities may be a result of compression by the interaction of the WIM with the gravitational well of the spiral arms and that it is on the path to becoming WNM.

Additional sensitive [CII] observations, along with those of [NII], are needed to trace the dynamics of the arm-WIM interaction.

In OT2 (PI: Velusamy) HIFI [CII] Mapping of 15deg longitude covering the 3-kpc and Norma tangencies and start of Perseus arm with adequate sampling (@ 40arcsec) is being observed. → more complete picture of the ISM gas properties and phases in spiral arm tangencies

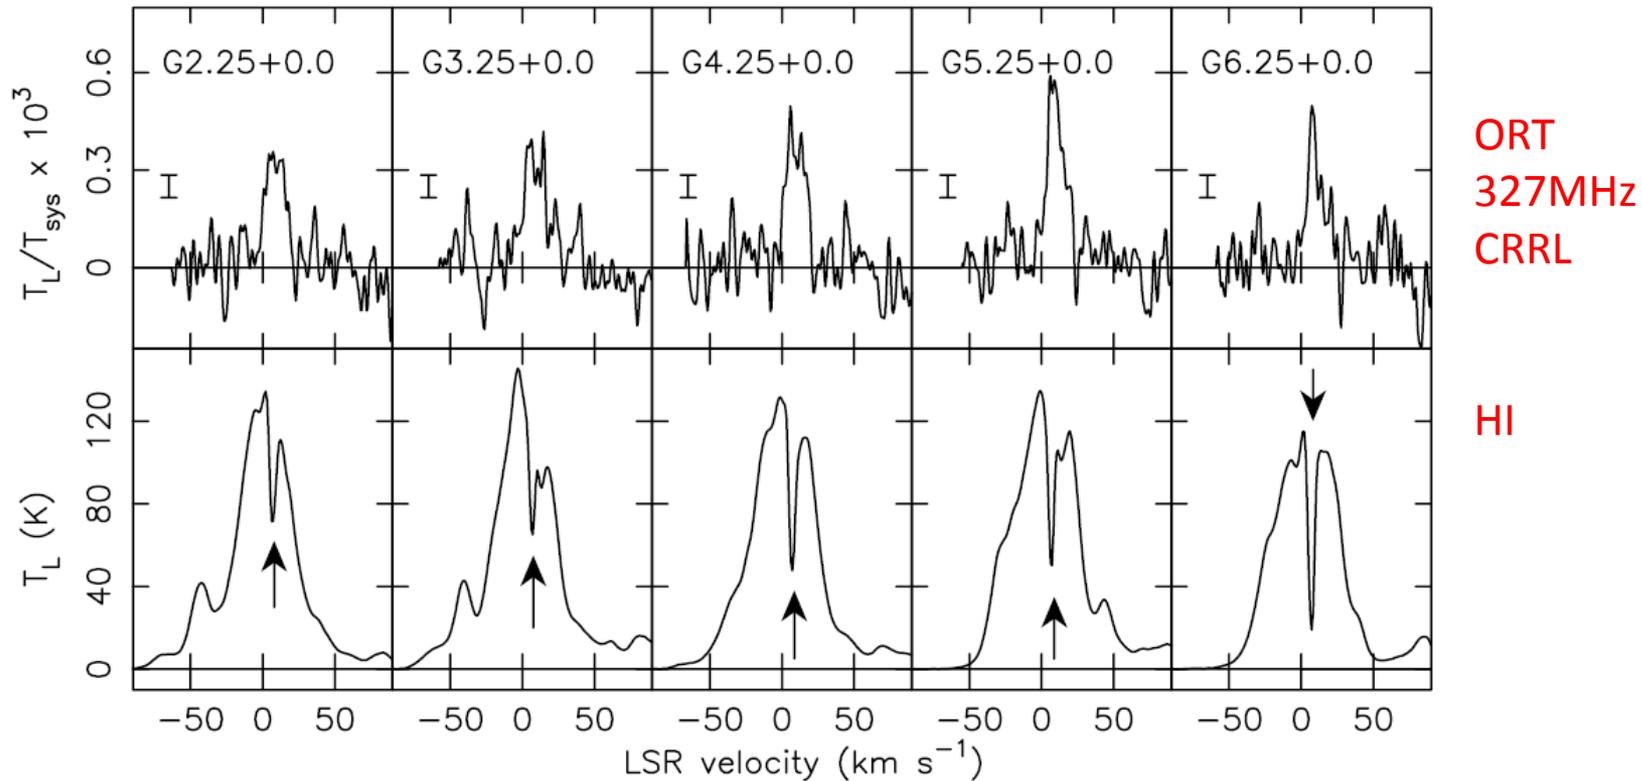

Ancillary data H- Radio recombination line survey of this region will be useful (possibility with GMRT 1.4GHz ?)

# ORT Carbon RRL in HI self absorbed cloud

Detailed modeling  
Work in progress

# [CII] emission as probe of SFR in galaxies

ISM thermal balance  $\rightarrow$  Heating = Cooling  
Primary source of heating is by UV radiation  
from star formation via SVGs and PHAs  
[CII] is a primary coolant  
Heating traced by e.g Spitzer IRAC 8um band  
Cooling traced by [CII] emission

- $\rightarrow$  [CII] emission is a measure of Star-formation rate (SFR)
  - $\rightarrow$  A tool for galaxy evolution throughout the universe
  - $\rightarrow$  At high redshifts 1.9THz [CII] line is observable in ALMA bands
- $\rightarrow$  NEED to understand Galactic [CII] emission.. for calibrating its use as tracer of SFR in external galaxies

# [CII] in GMC in M33

CII emitting gas closely linked to molecular gas:

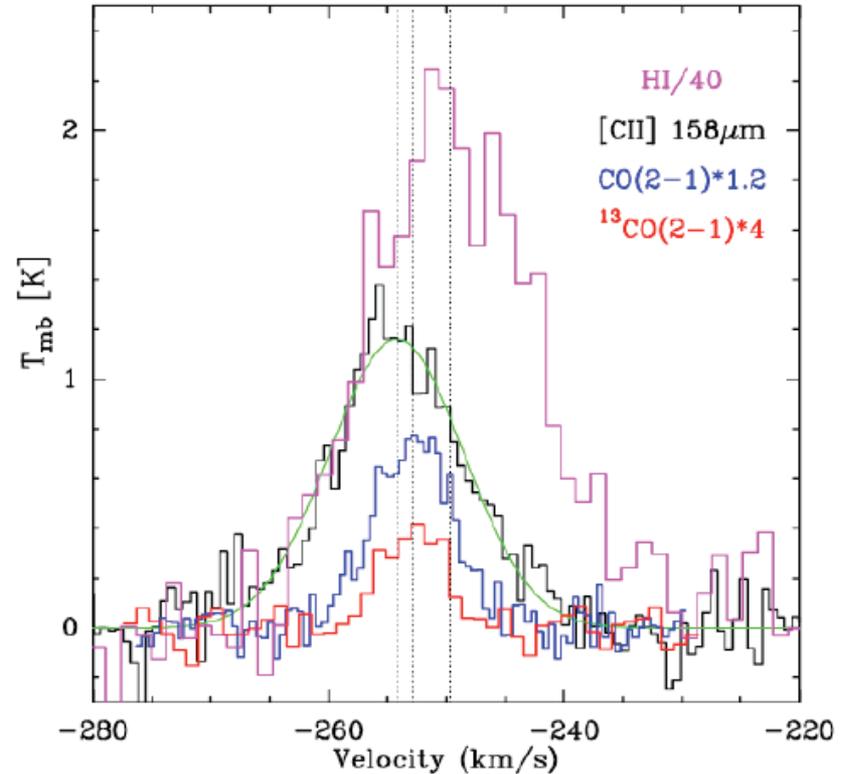

CO found but **not** proportional to CII emission

CII follows dust and H $\alpha$  emission with 24 and 100  $\mu\text{m}$

No "diffuse" CII emission detected, whether related to HI or WIM

Model where GMCs are surrounded by some H<sub>2</sub> w/o CO seems justified

$\text{SFR} \propto I(\text{CII})^{1.5}$  in a star forming region

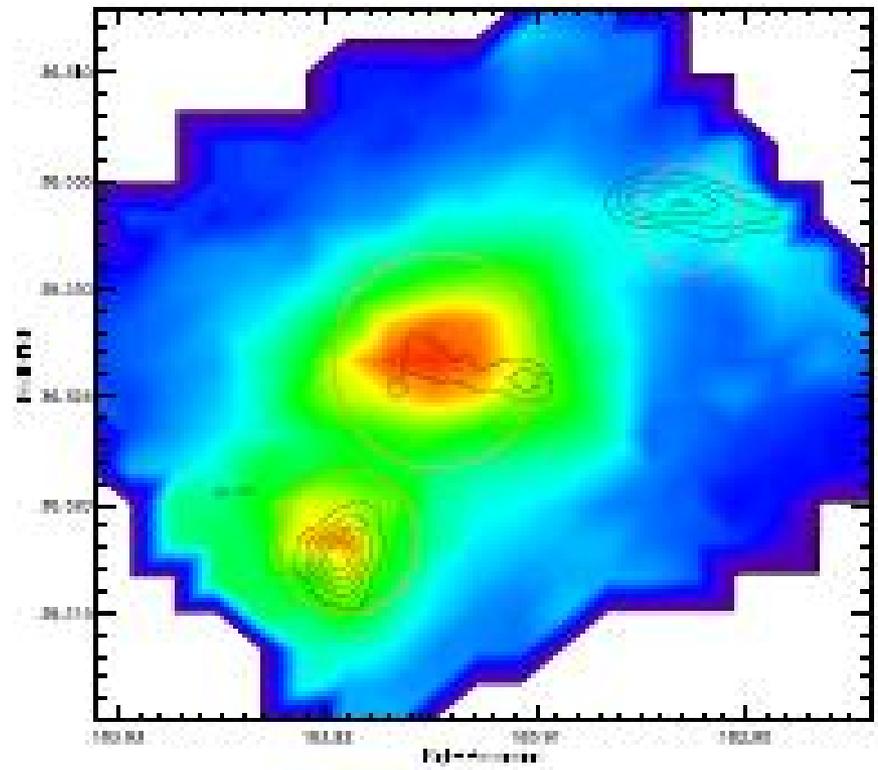

Mookerjea+ 2011

# [CII] NGC 4214

CO contours overlaid on [CII] image:

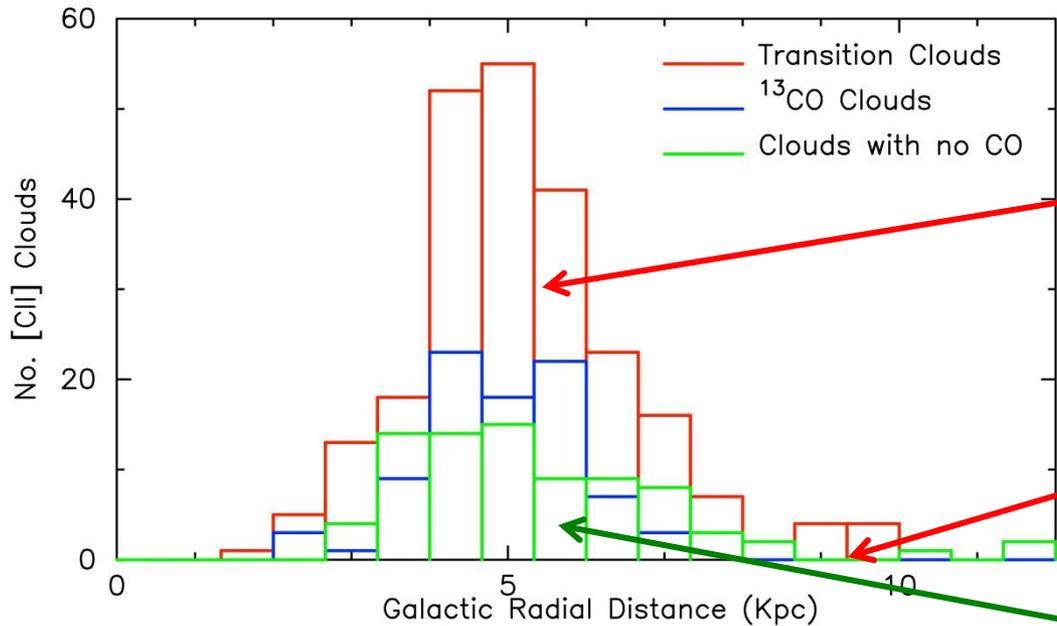

- extreme  $L_{[\text{CII}]} / L_{\text{CO}}$  values
- the low metallicity and clumpy ISM:
- a consequence of the lower dust abundance
  - Deep penetration of FUV into molecular clouds, photodissociating the CO
  - larger  $\text{C}^+$  emitting envelope surrounding a small CO core.

Sue Madden 011

# Global properties of Galactic 158 $\mu\text{m}$ [CII] emission

## Distribution of [CII] Clouds with $R_{\text{Gal}}$

~ 60% of Transition Clouds are located at  $R = 4 - 6$  kpc

Few clouds detected in local ISM ( $R \sim 8$  kpc)

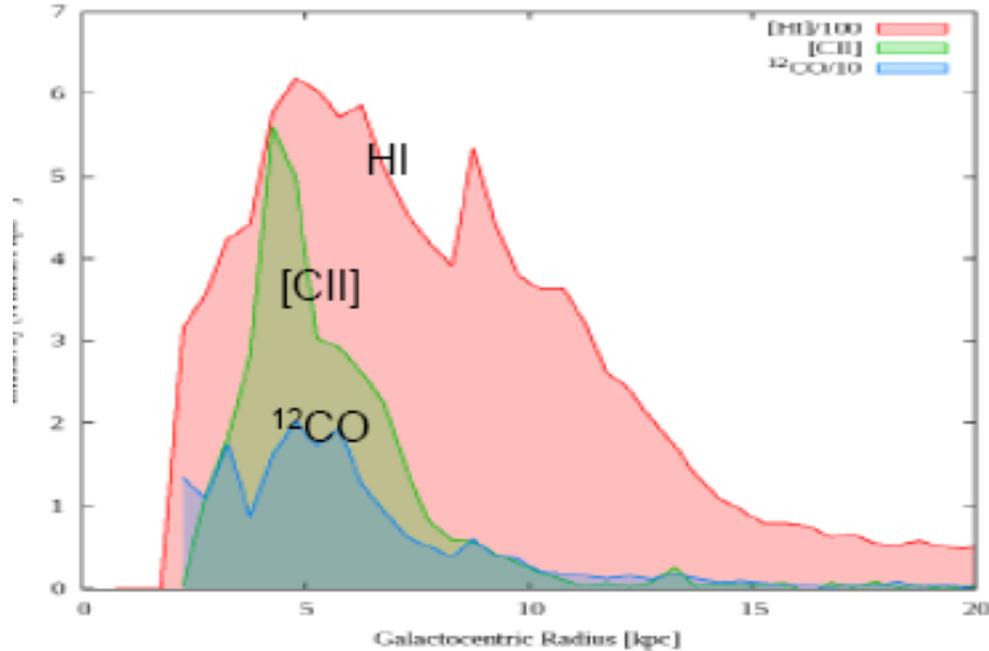

[CII] clouds with no CO have a flatter radial distribution

- 429 [CII] narrow components (in a small sample in the inner Galaxy)
- HI associated with all CII Clouds
- 88 have no CO emission
- 247 with  $^{12}\text{CO}$ , but no  $^{13}\text{CO}$
- 94 with  $^{13}\text{CO}(1-0)$  emission

# Global properties of Galactic 158 $\mu\text{m}$ [CII] emission

## Radial distribution of [CII], HI, $^{12}\text{CO}$ intensities

Pineda, Langer, Velusamy, Goldsmith, 2012

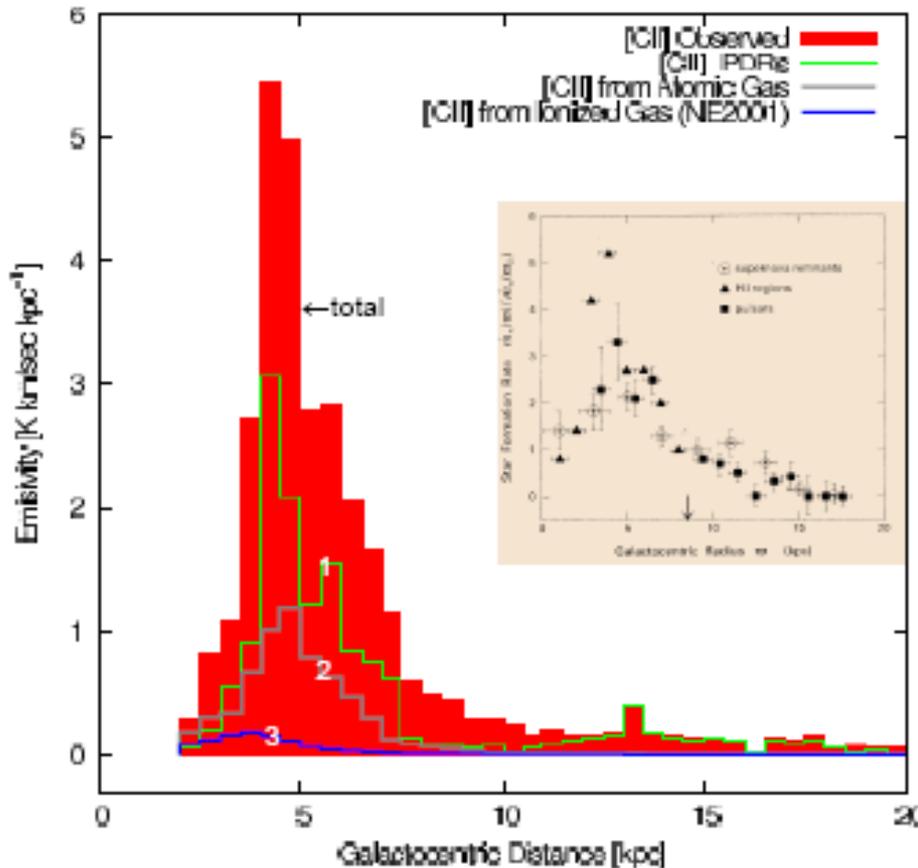

Galactocentric distribution of the [C II], HI, and CO integrated intensity. Note the concentration of [CII] in the inner Galaxy within 7 kpc radius (peak near 5kpc) suggesting that it is tracing the UV field and hence the star formation in the Galaxy.

# Global properties of Galactic 158 $\mu\text{m}$ [CII] emission:

## Preliminary results on Relative ISM contribution to [CII] intensity

Pineda, Langer, Velusamy, Goldsmith, 2012

→ We find that in the Galaxy at least 70% of the [CII] intensity is tracing star formation. (work in progress)

Relative contribution to the observed total [CII] intensity from different ISM components:

1. (green line) represents [CII] emission from PDRs (traced by  $^{13}\text{CO}$  emission defining the warm molecular gas);
2. (grey line) represents [CII] emission from the HI gas, estimated for cloud gas pressure of  $10^4 \text{ K cm}^{-3}$ ;
3. (blue line), the [CII] emission from ionized gas, estimated for the NE2001 electron density model (Cordes & Lazio 2002).

The remaining [CII] intensity (about 30%) is tracing the “dark  $\text{H}_2$  gas”, in which hydrogen is primarily in  $\text{H}_2$  and carbon transitioning from  $\text{C}^+$  to  $\text{CO}$ .

(inset) Distribution of the Galactic SFR (reproduced from Stahler & Palla, 2005)

# Summary

- The 1.9 THz [CII] line (at 158  $\mu\text{m}$ ) is often the single brightest emission line in galaxies.
- The [CII] emission in the ISM can arise from a wide range of temperatures excited by collisions with electrons as well as atomic and molecular hydrogen.
- [CII] line is a primary coolant , thus extremely useful as a robust tracer of total gas mass and a quantitative Star Formation Rate (SFR) measure for high-redshift galaxies.
- Herschel HIFI and PACS spectroscopy are enormously successful studying [CII]
- GOTC+ survey of Galactic [CII] emission reveals new details on the distribution and characteristics of the warm, dense and atomic and molecular components of the interstellar medium: WIM, WNM, CNM, including the so-called "dark H<sub>2</sub> gas" in cloud transitions which is missed by both HI and CO as tracers.
- GOT C+ results on the global distribution of [CII] emission and its characterization as function Galactic radius is a first step towards calibrating the [CII] emission as a probe for Star Formation Rate (SFR) in external galaxies.
- More to follow in Herschel OT1 & OT2 observations
- New opportunities on SOFIA with GREAT and in future with array receivers
- The high luminosity of [CII] makes the 158  $\mu\text{m}$  line readily detectable beyond  $z = 5$  in ALMA bands.
