There are 200 billion stars in our galaxy...

There ought to be some other Earths.

Ways to See Exoplanets

Star wobble (Radial Velocity)
distance from star

Mass, orbital period and shape:

Star dimming (Transit photometry)
from star

Size, orbital period: distance

Star wobble (Astrometry)

Direct imaging

Microlensing

Pulsar timing

Reflection photometry

Ways to See Exoplanets

Star wobble (Radial Velocity)
distance from star

Mass, orbital period and shape:

Star dimming (Transit photometry)
from star

Size, orbital period: distance

With both mass and size get planet
density. Then can tell if the planet is:

Gas : Low density

Ice : Medium density

Rock : High density

How do we know it when we find
another Earth?

Look for Habitable Planets

Look for Habitable Planets

- Right temperature
- Liquid water
- Atmosphere

Look for Habitable Planets

- Right temperature
- Liquid water
- Atmosphere

Planets come in several sizes

Too big (about $>10 M_{\text{earth}}$)

Holds onto light gases (Hydrogen and Helium) too well and turns into a gas giant.
(Jupiter, Saturn, Uranus, Neptune)

Just right ($0.5 - 10 M_{\text{earth}}$)

Holds on to heavier gases (Nitrogen, Oxygen) long enough to have a potentially habitable atmosphere (Earth, Venus)

Too small (about $<0.5 M_{\text{earth}}$)

Can't hold onto a life sustaining atmosphere.
(Moon, Mercury)

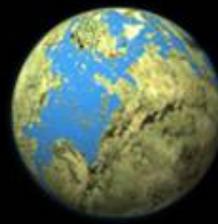

And a range of temperatures

Too hot!

(too close)

Just right

Too cold!

(too far)

The Habitable Zone

The region around a star where liquid water might exist on a planet's surface

The Goldilocks Zone

Hotter Stars

F0

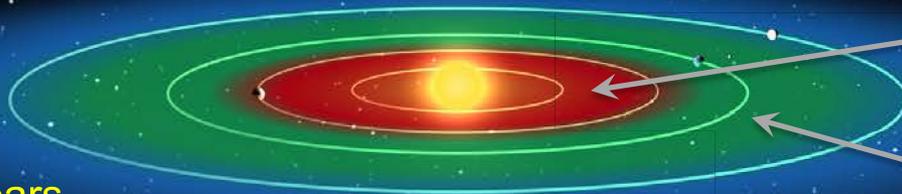

2 to 10 year orbits

Sunlike Stars

G2

9 months to 3.5 years

Too hot

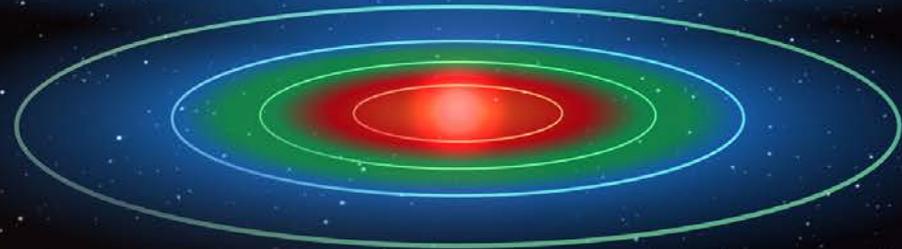

Too cold

Just right

Cooler Stars

K5

3 to 13 months

Transits Won't Find ALL Planets

Not all planetary orbits are aligned to produce a transit

$$\text{) Range of Pole Positions} = \frac{d^*}{R_p}$$

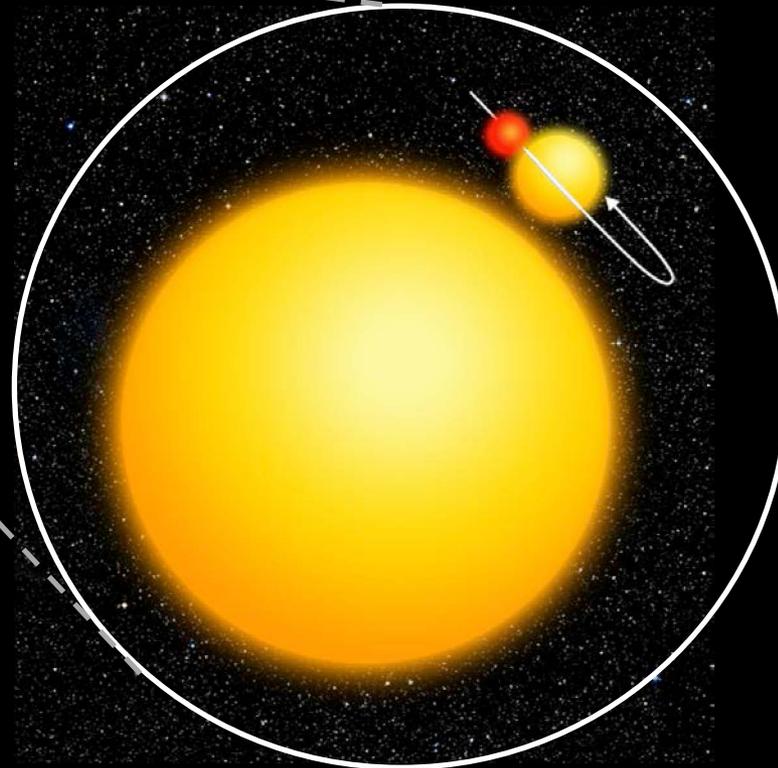

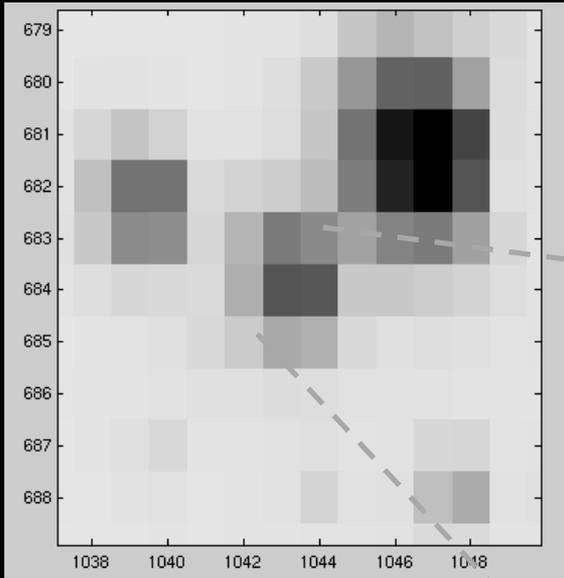

Only a few percent chance for a given planet to transit

Earth and Sun have only 0.5% chance

Transits last only a few hours each orbit

Must stare constantly at many thousands of stars to find many planets.

A pitfall: False Positives

Other things can look like transiting planets.

Eclipsing binary stars behind target stars

Candidate transiting planets need to be carefully examined to look for false positives.

RV measurements good for finding large planets

Also Earth-size around small, cool stars

Not good enough to find Earths around Sun-like stars

Also too slow.

Can only do 1 star at a time.

Need many measurements totaling, maybe, hundreds, of hours

Transit searches from the ground good for finding lots of large planets.

Not good enough to find Earths around Sun-like stars

Need another way to find Earths.

Kepler Telescope-Photometer

Wide field for lots of stars

15° diameter field

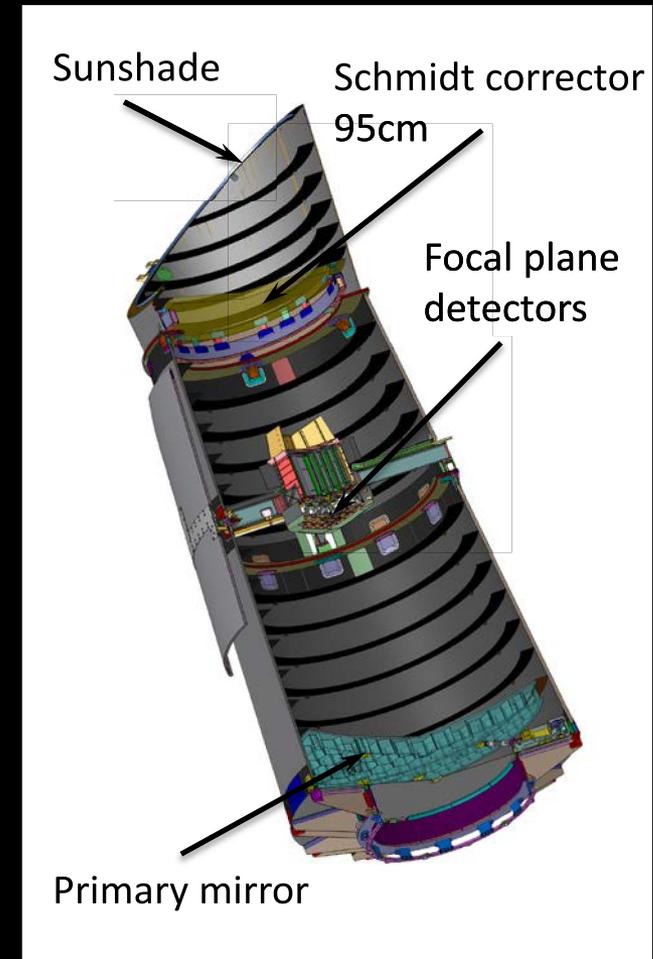

Monitor 150,000 stars at once

Big, to get enough light

95 cm aperture

Build it for use in space

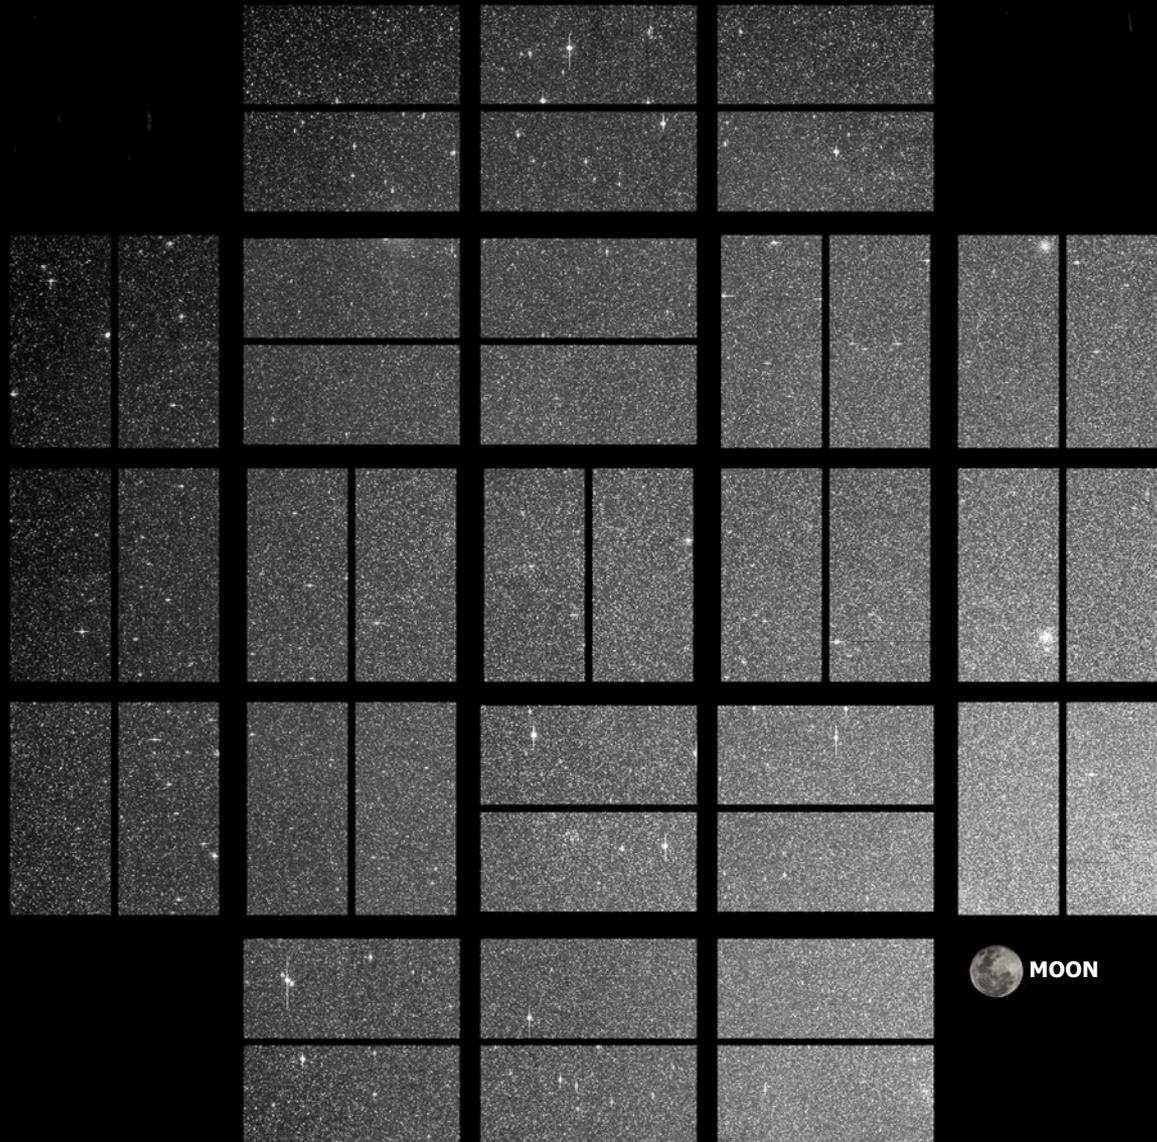

No variability from atmosphere to mask small transits

Planet Candidates

As of February 27, 2012

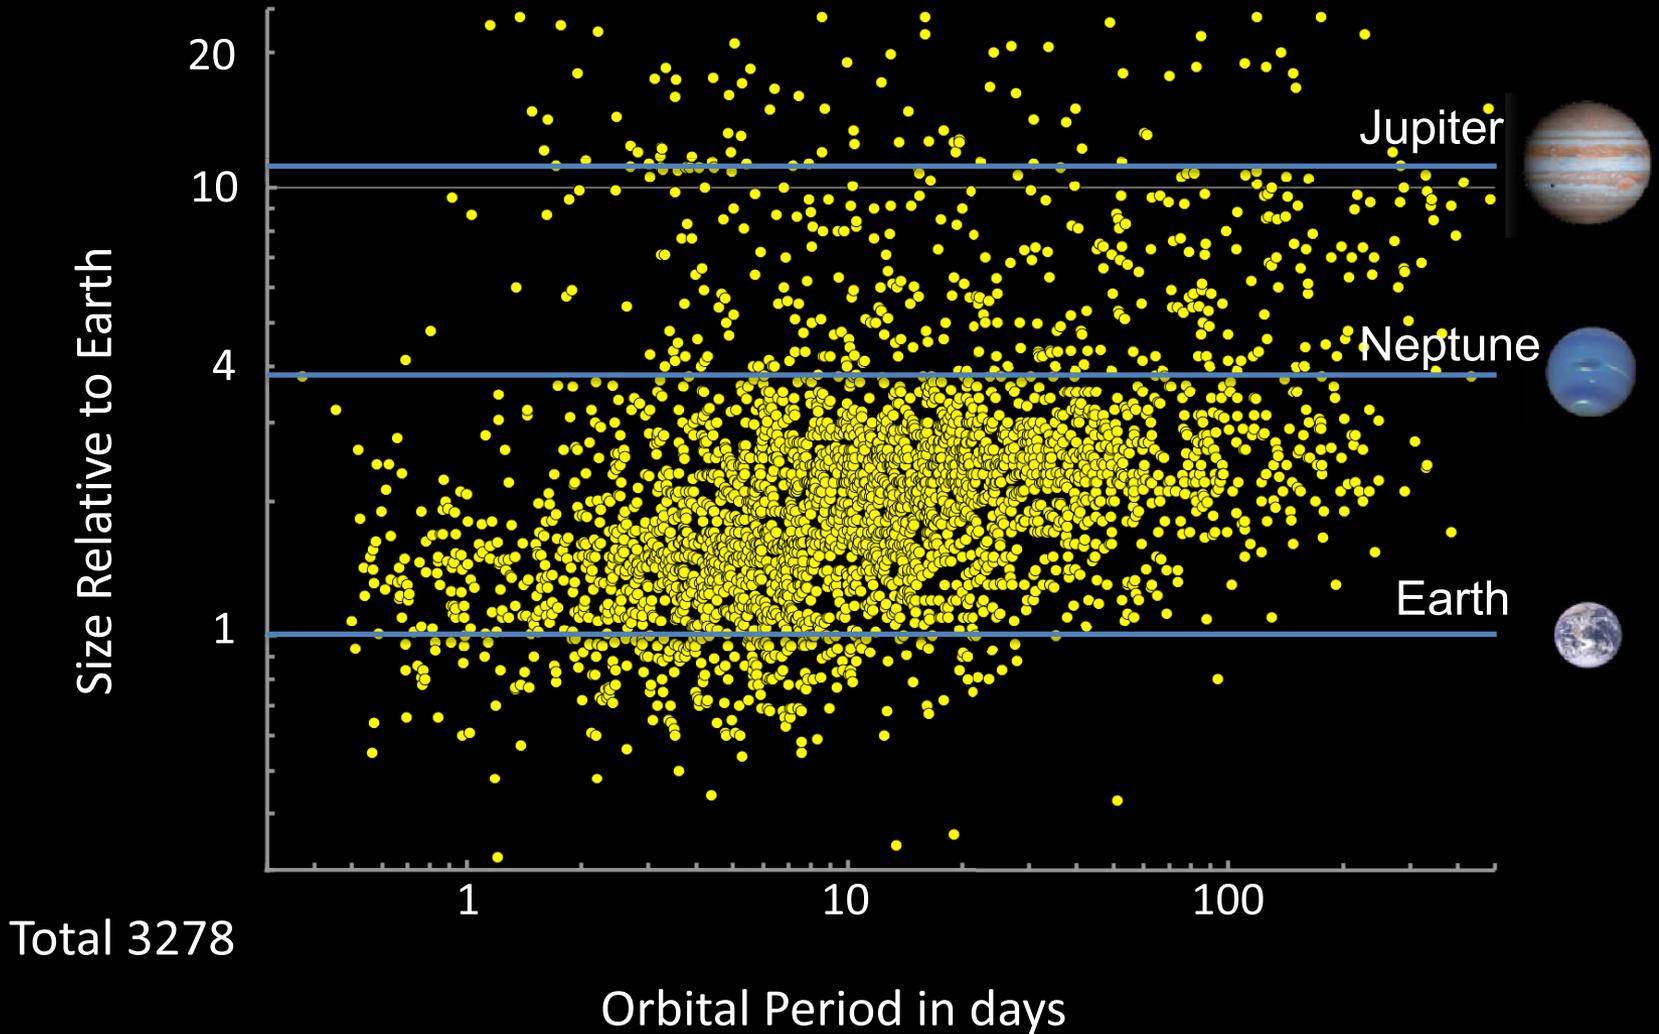

Planet Candidates

As of January 7, 2013

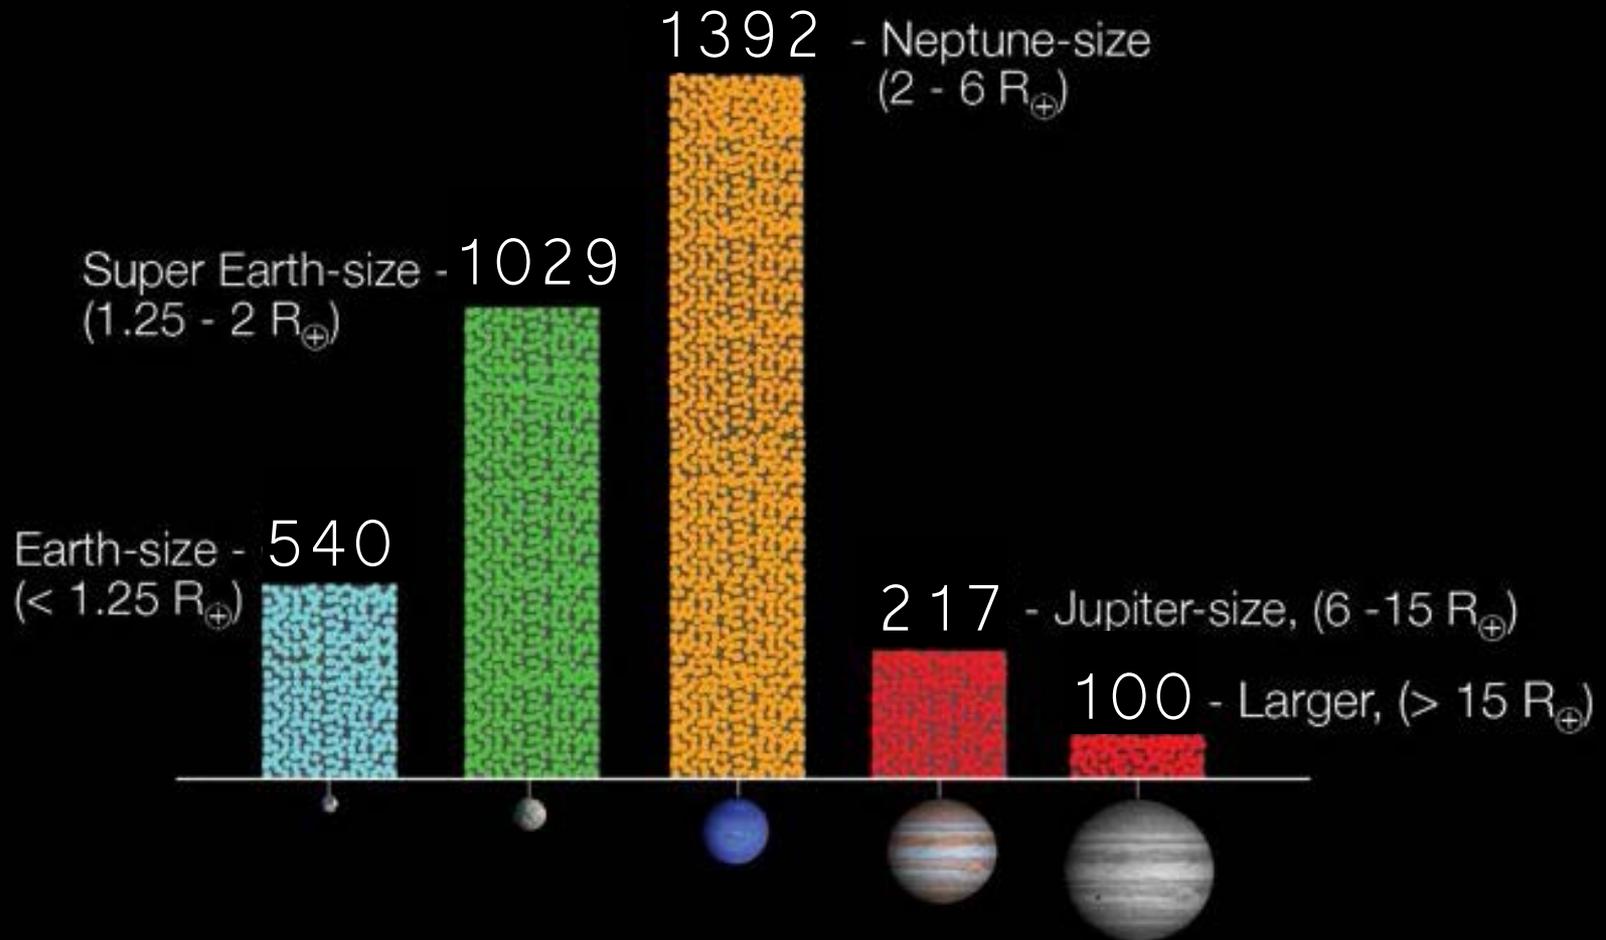

Candidates as of July 2013

36 Months of data

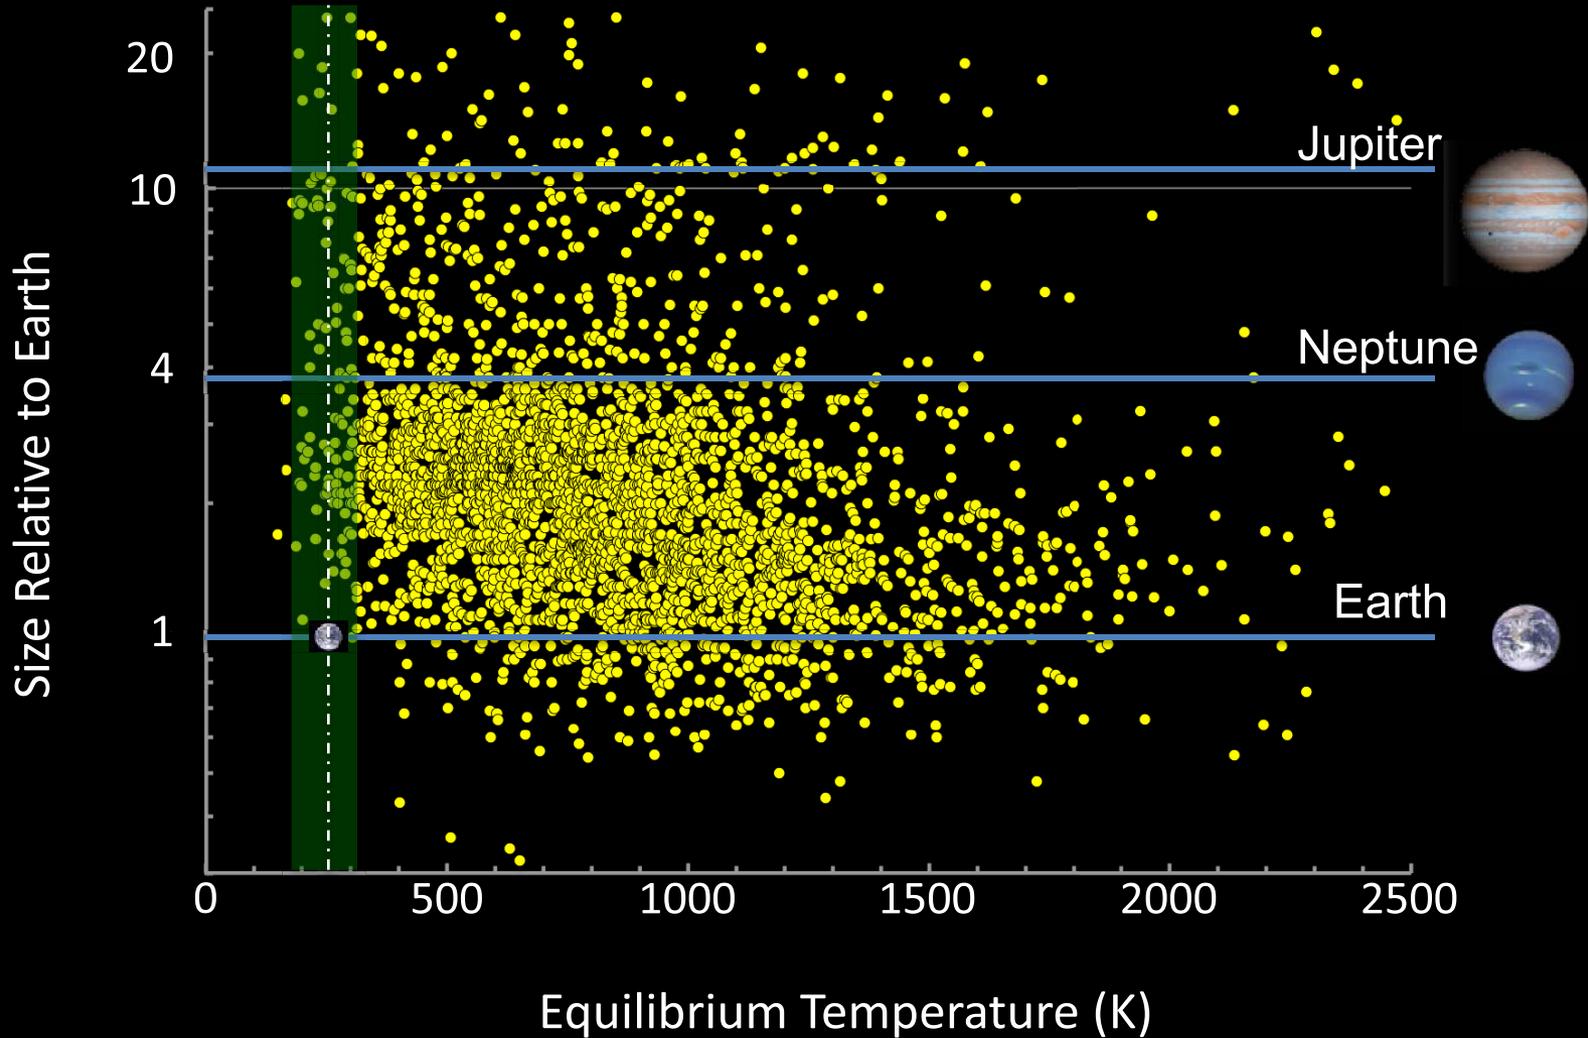

Taking the Planetary Census

Candidates as of July 2013

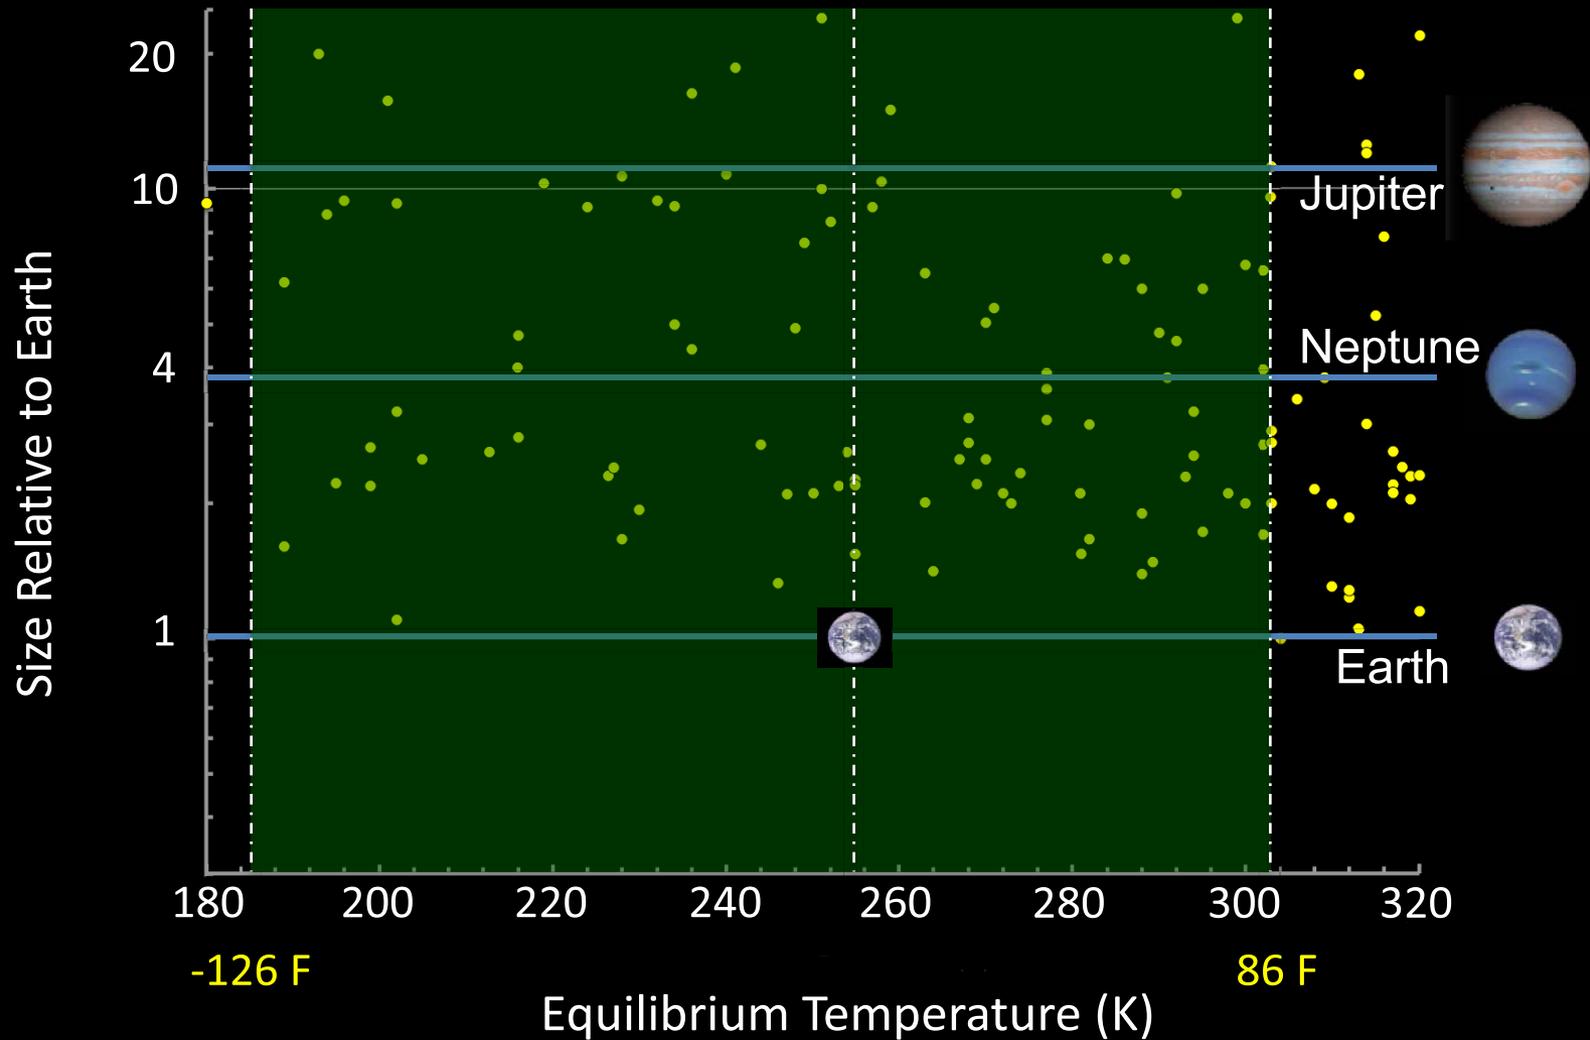

36 Months of data

Candidates as of July 2013

36 Months of data

Kepler-16b

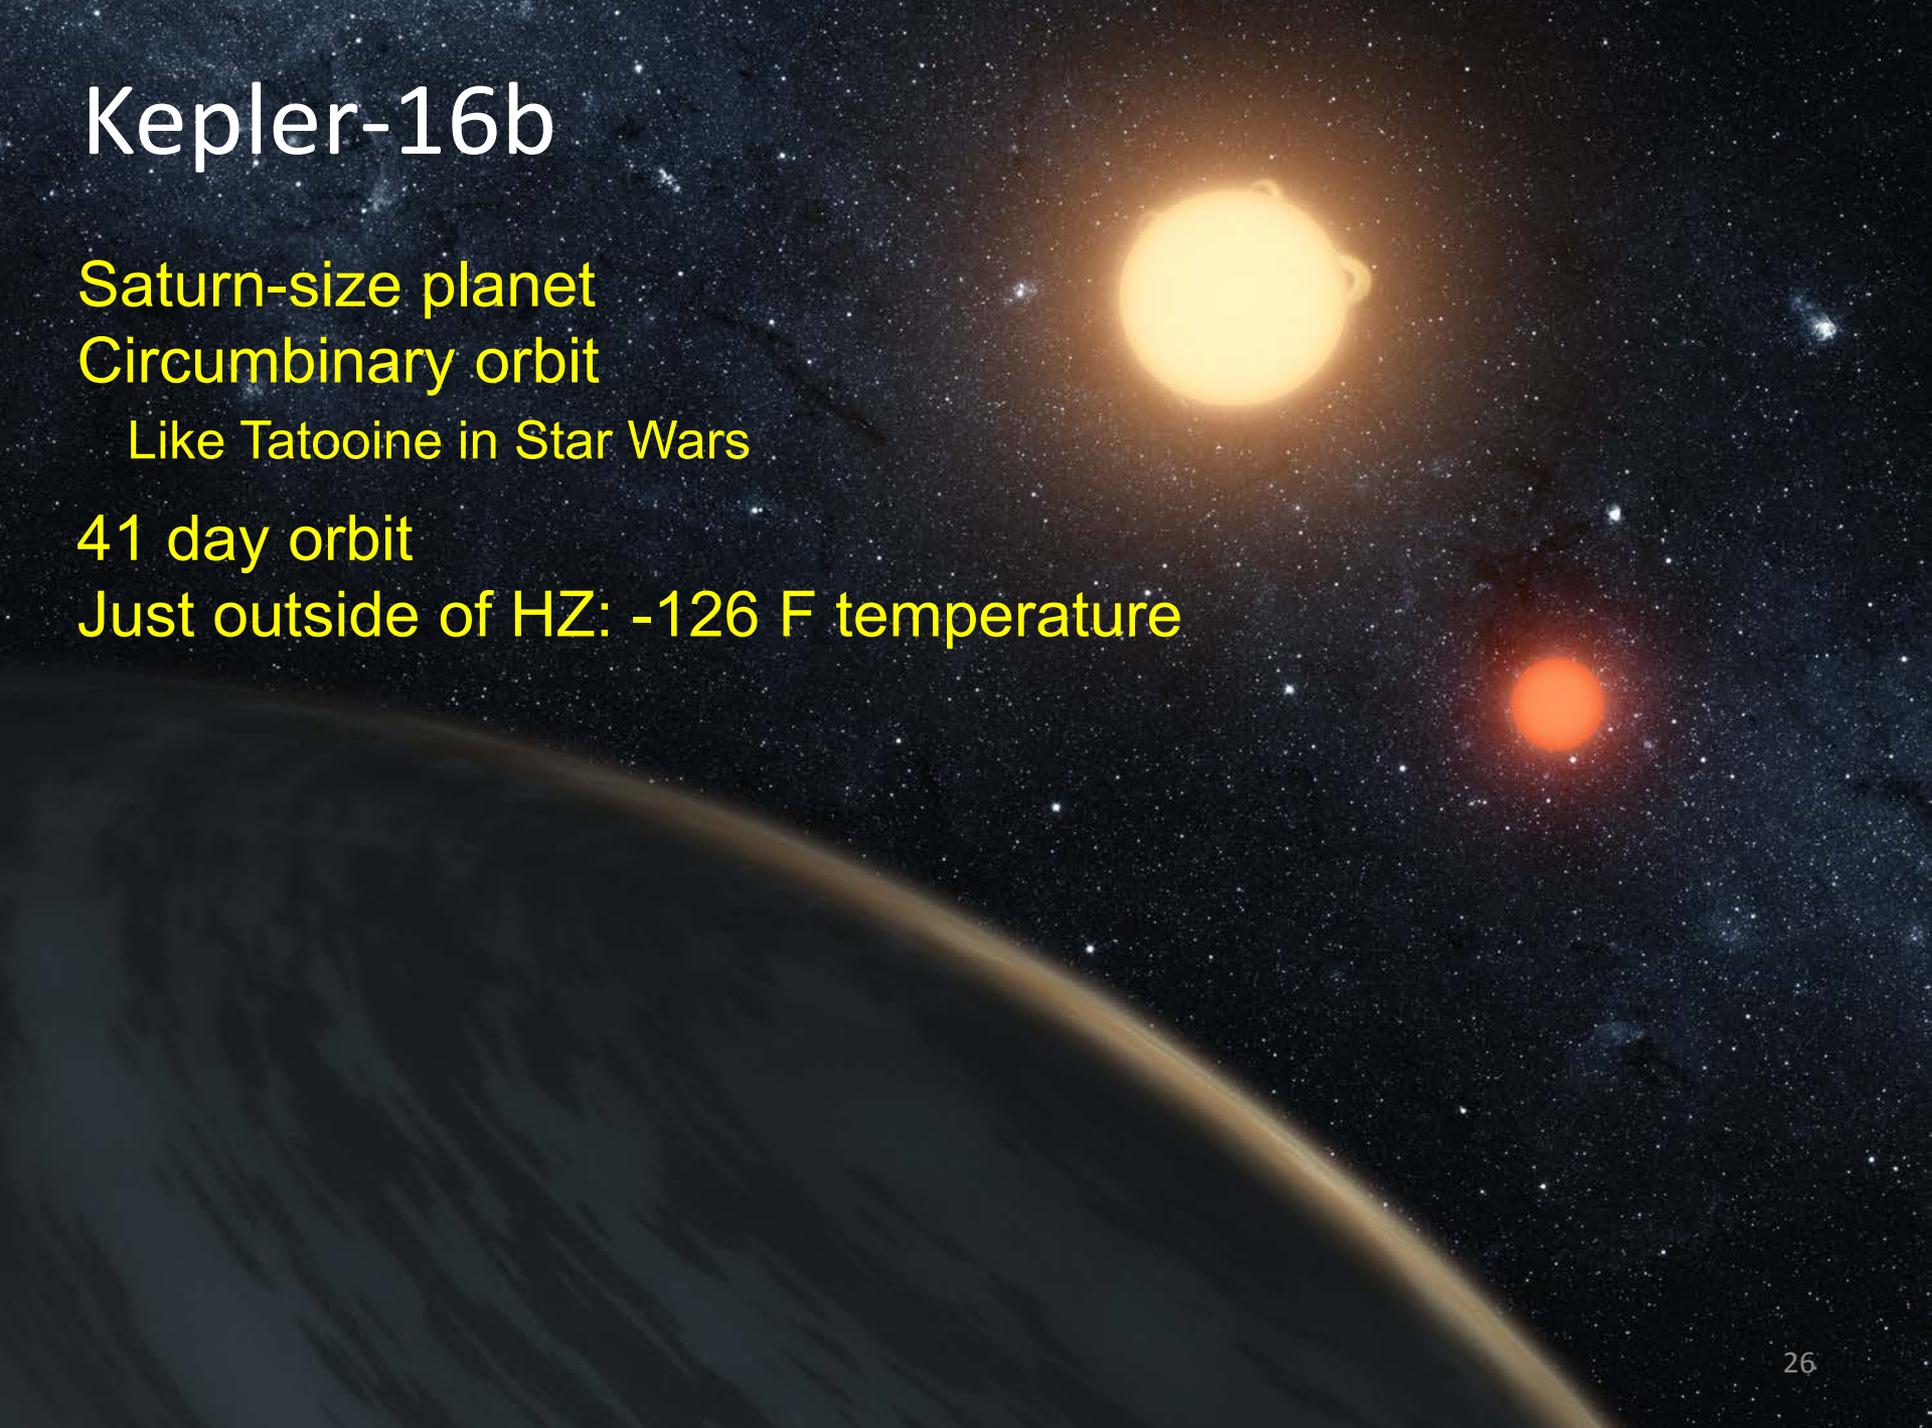

Saturn-size planet

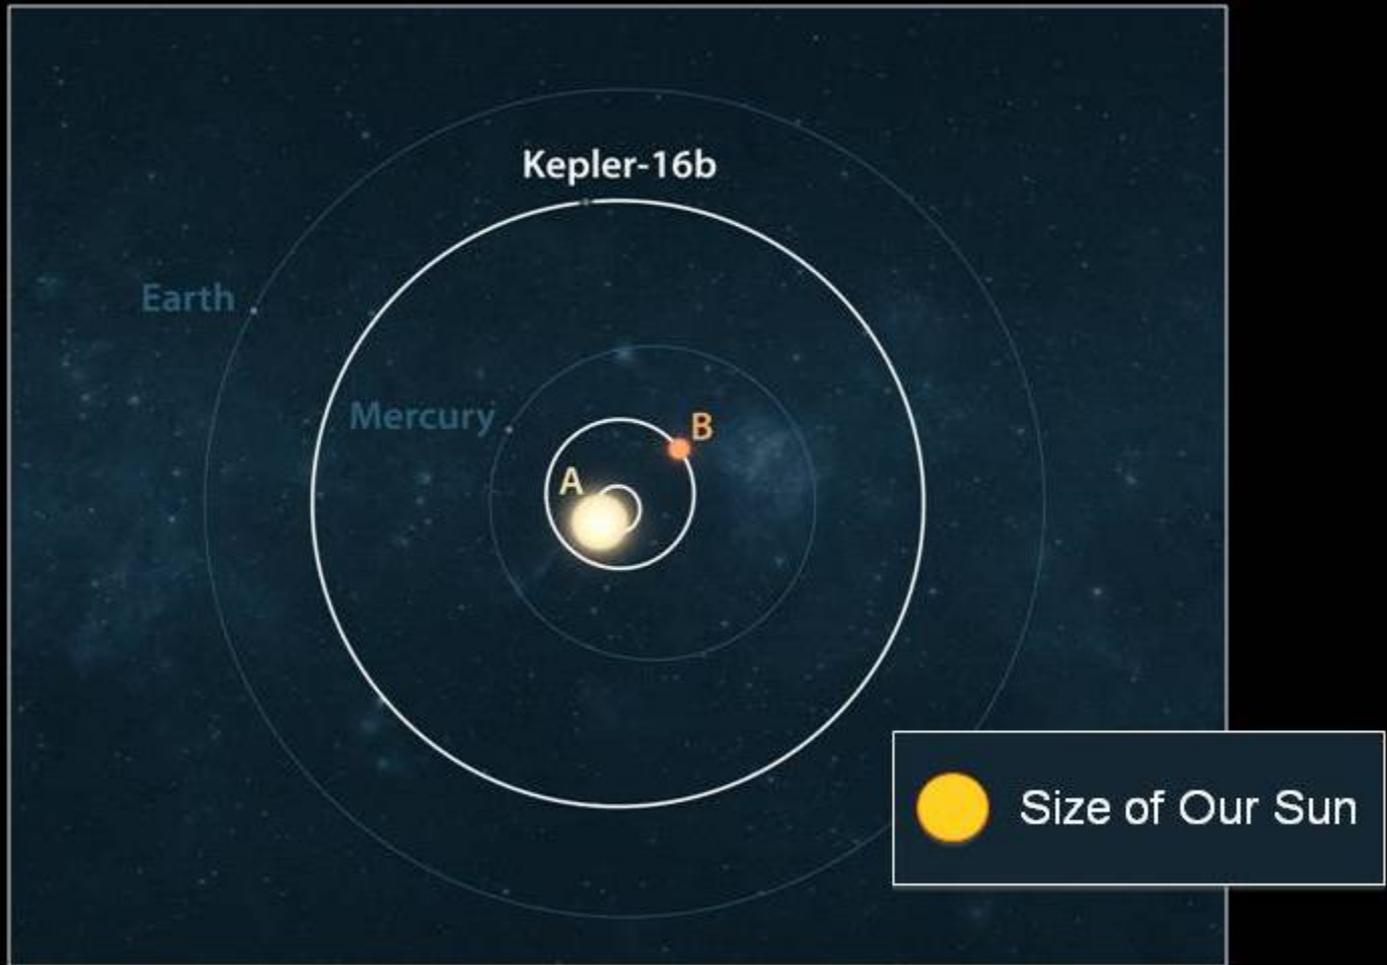

Circumbinary orbit

Like Tatooine in Star Wars

41 day orbit

Just outside of HZ: -126 F temperature

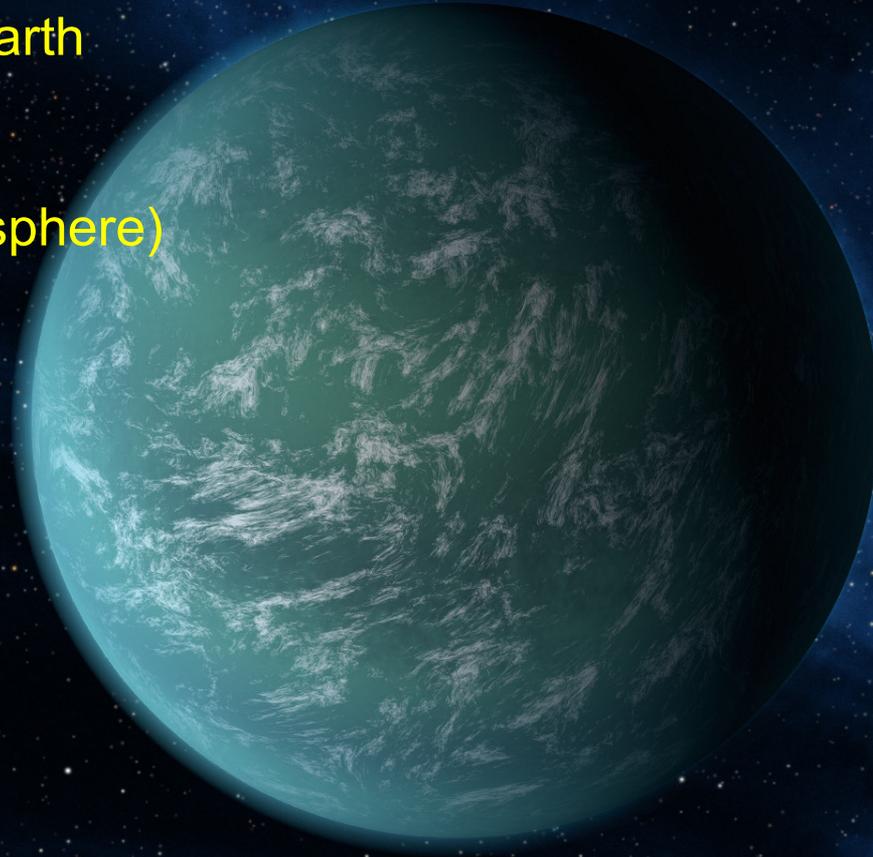

Sunset on a possible moon of Kepler 16b

We now know of 5 more planets in 3 other systems with two suns!
Circumbinary planets must be fairly common.

Kepler 22b

In the habitable zone of a Solar-like star
but 2.4 times the size of Earth

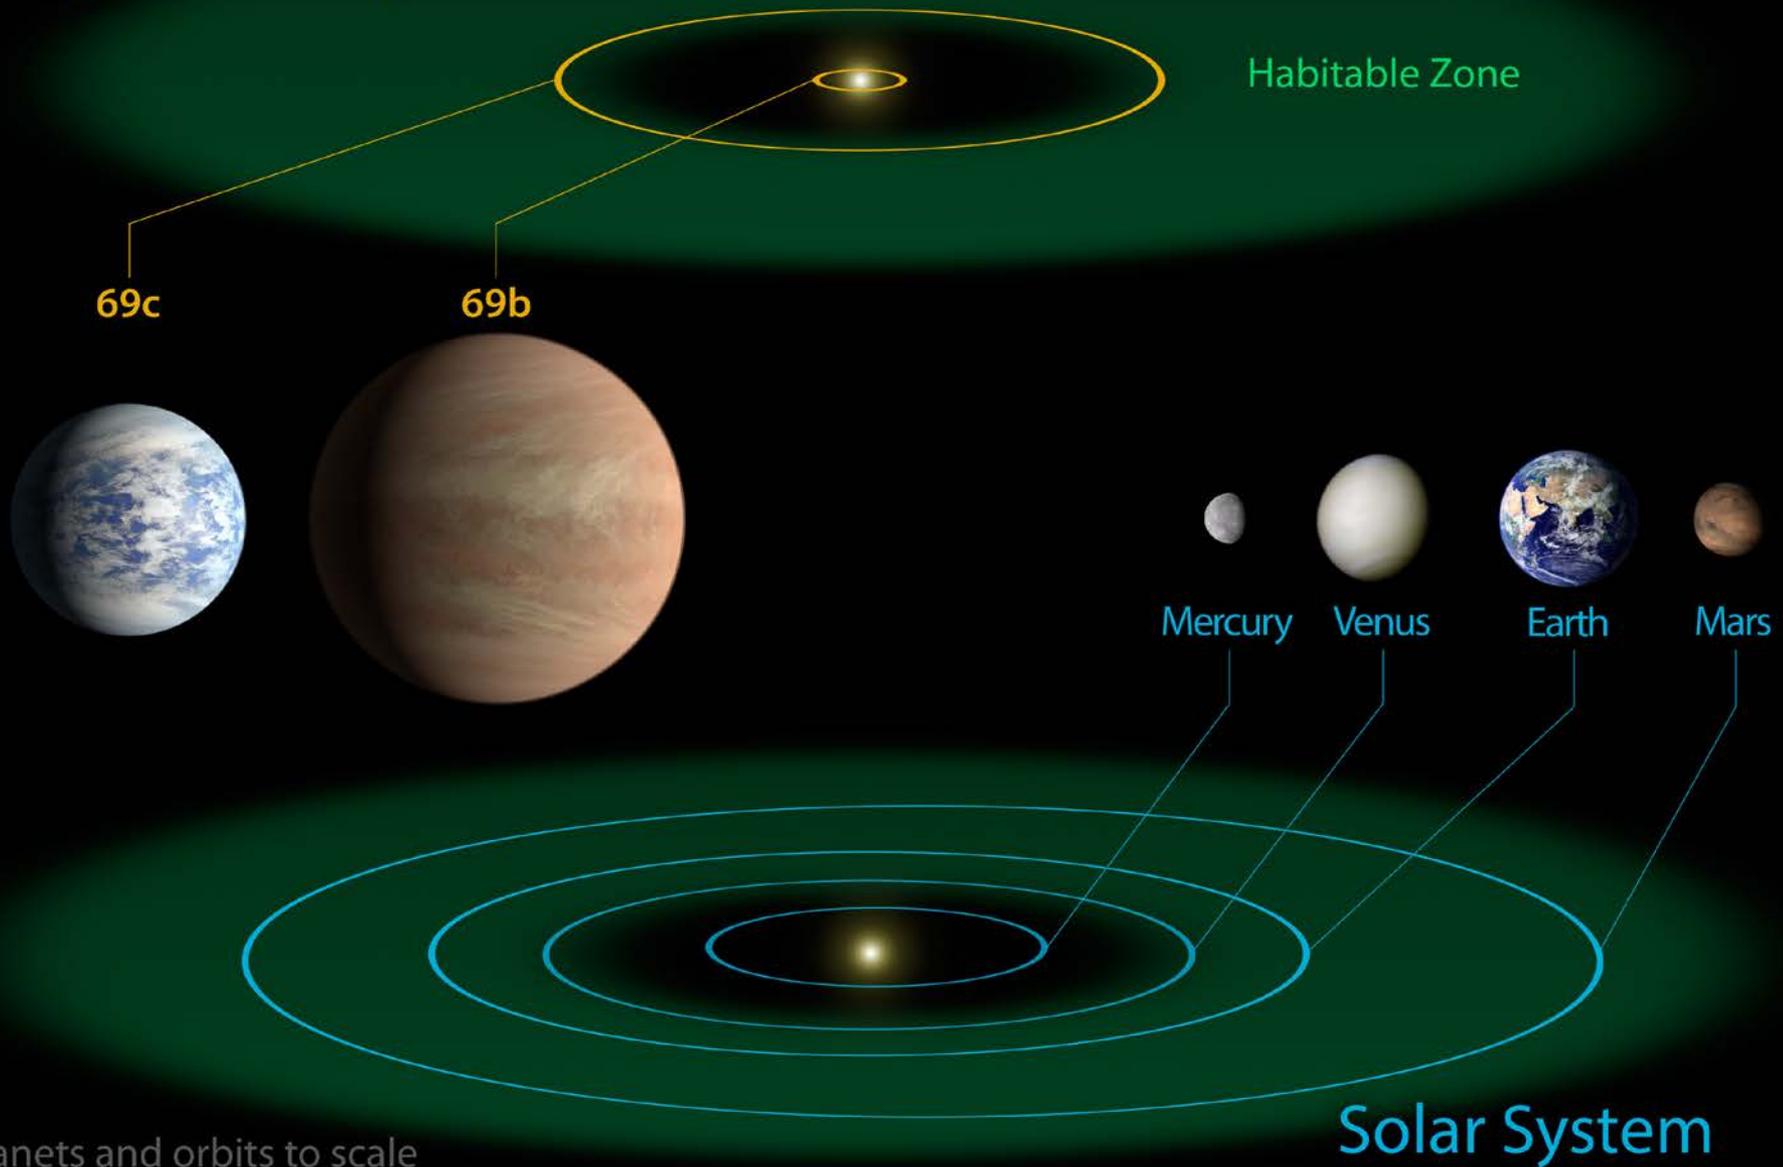

Temperature 14 F
(but warmer with an atmosphere)

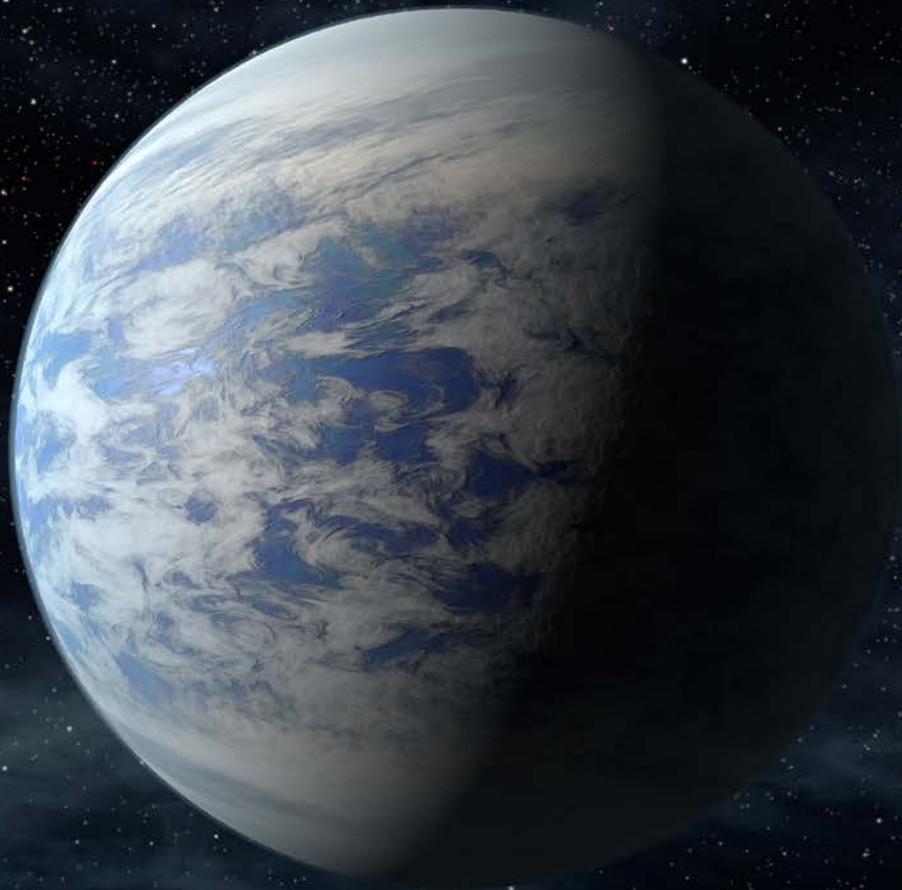

Water planet?
Rocky surface?
Deep atmosphere?

Kepler-22	G8 Dwarf
Mass:	.97 M_{Sun}
Radius:	.98 R_{Sun}
Luminosity:	.66 L_{Sun} ²⁹

Kepler-69 System

Kepler-69c

Teq: 299K / 79F

Size: $1.7 R_{\text{Earth}}$

Mass: unknown

Composition: probably rocky

Kepler-69

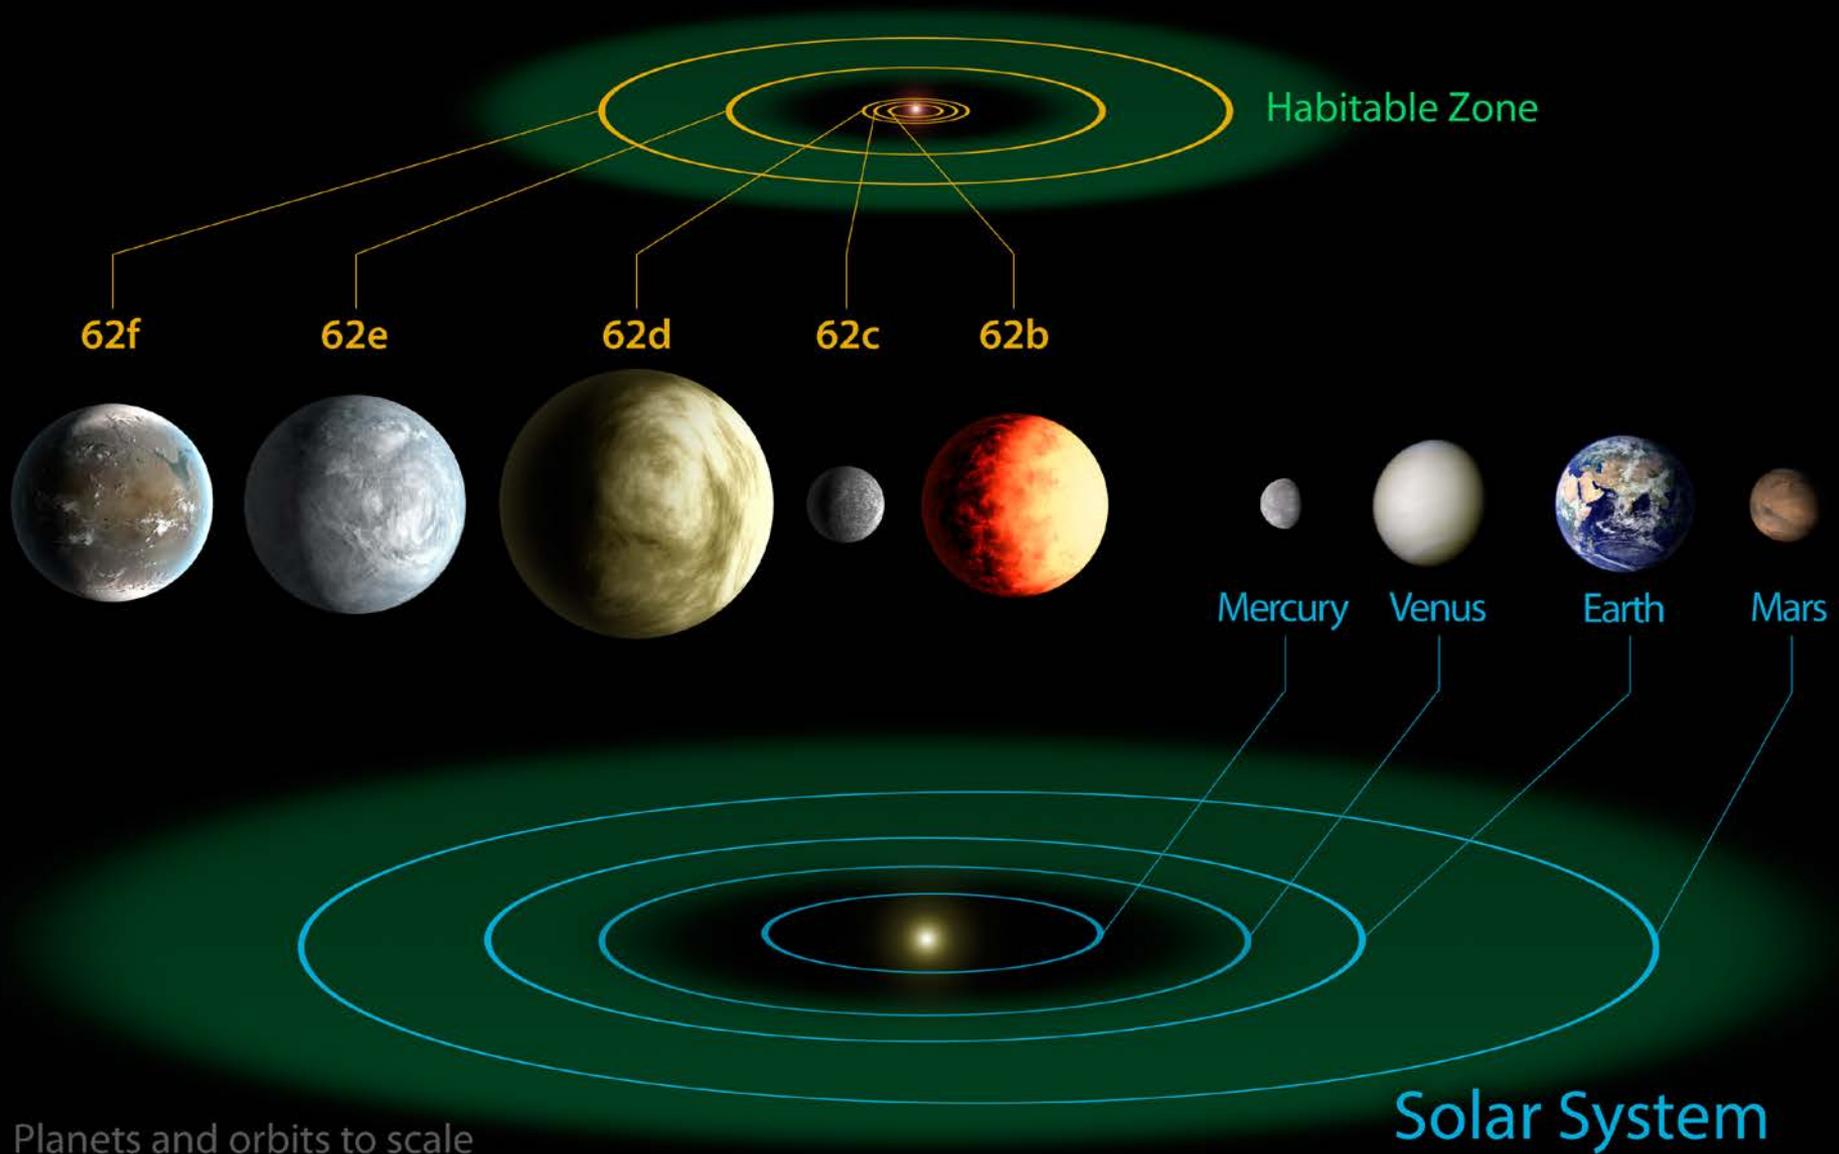

G6 Dwarf

Mass: $.81 M_{\text{Sun}}$

Radius: $.93 R_{\text{Sun}}$

Luminosity: $.75 L_{\text{Sun}}$

Kepler-62 System

Kepler-62f

T_{eq} : 208K / -85F

Size: $1.4 R_{Earth}$

Mass: uncertain ($<43 M_{Earth}$)

Composition: probably rocky

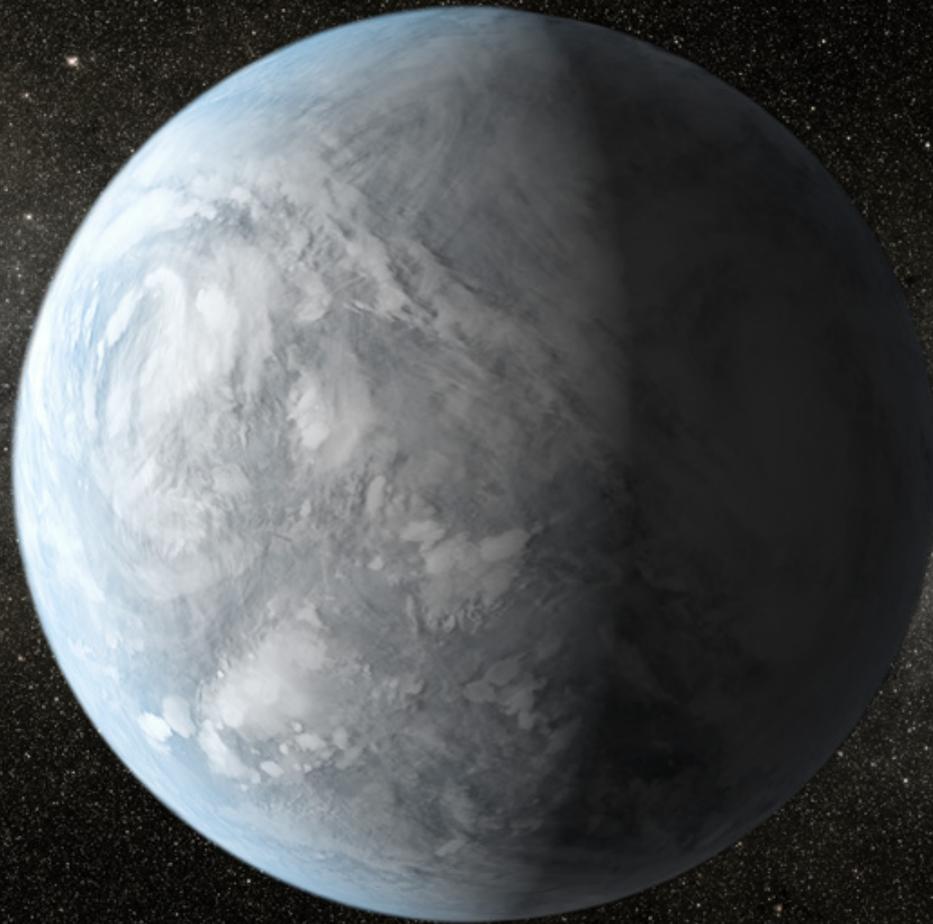

Kepler-62

K2 Dwarf

Mass: $.69 M_{Sun}$

Radius: $.64 R_{Sun}$

Luminosity: $.30 L_{Sun}$

Kepler-62e

Teq: 270K / 27F

Size: $1.6 R_{\text{Earth}}$

Mass: uncertain ($<36 M_{\text{Earth}}$)

Composition: probably rocky

Kepler-62

K2 Dwarf

Mass: $.69 M_{\text{Sun}}$

Radius: $.64 R_{\text{Sun}}$

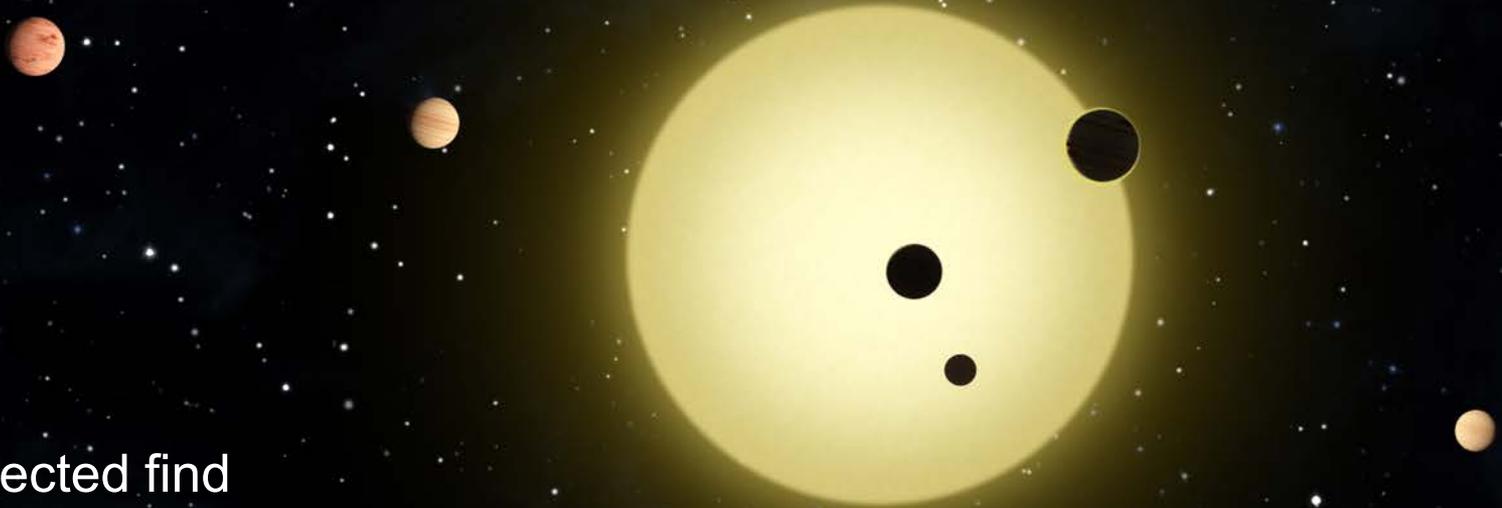

Luminosity: $.30 L_{\text{Sun}}$

Multiple Planet Systems

Unexpected find

Tells us about planet systems, not just planets

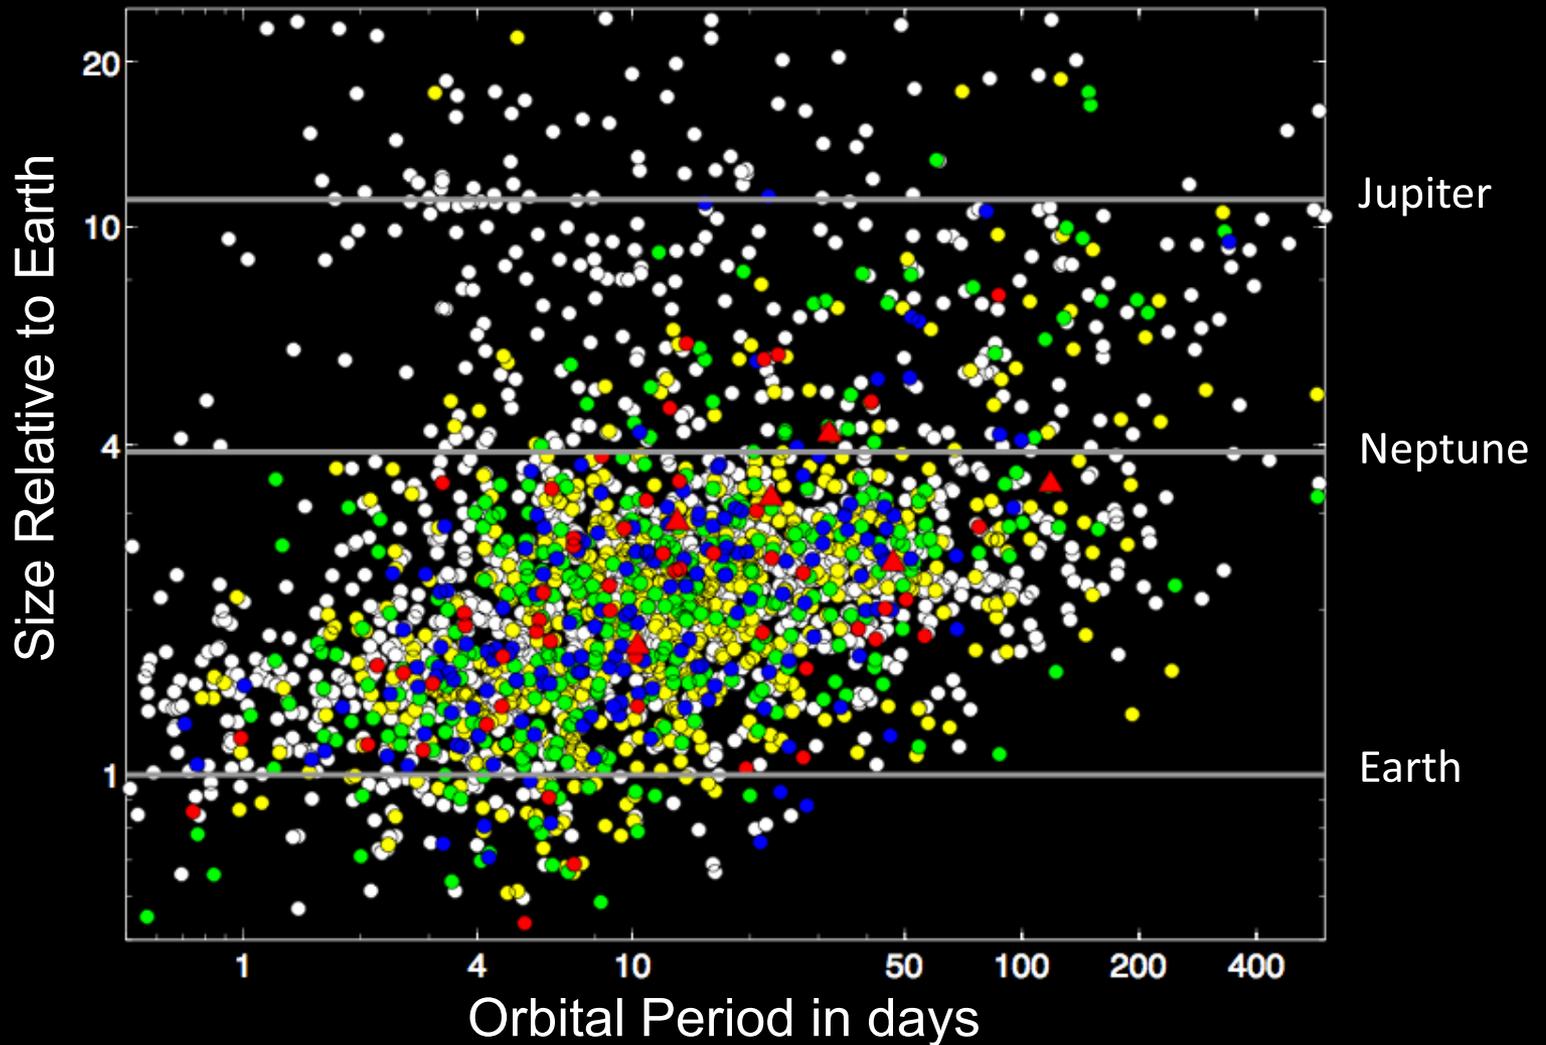

Self confirming because multiple occurrence of false positives is really unlikely

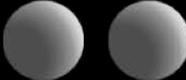

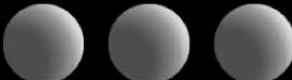

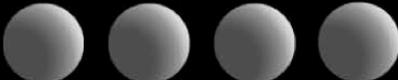

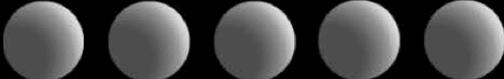

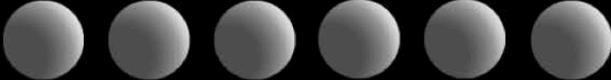

Multiple Systems

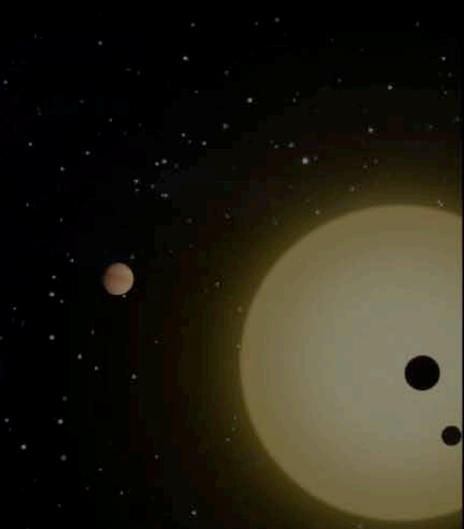

● one - 1425 ● two - 490 ● three - 252 ● four - 108 ● five - 40 ▲ six - 6

Kepler Transiting Multi-Candidate Systems

Kepler Census – May 2013

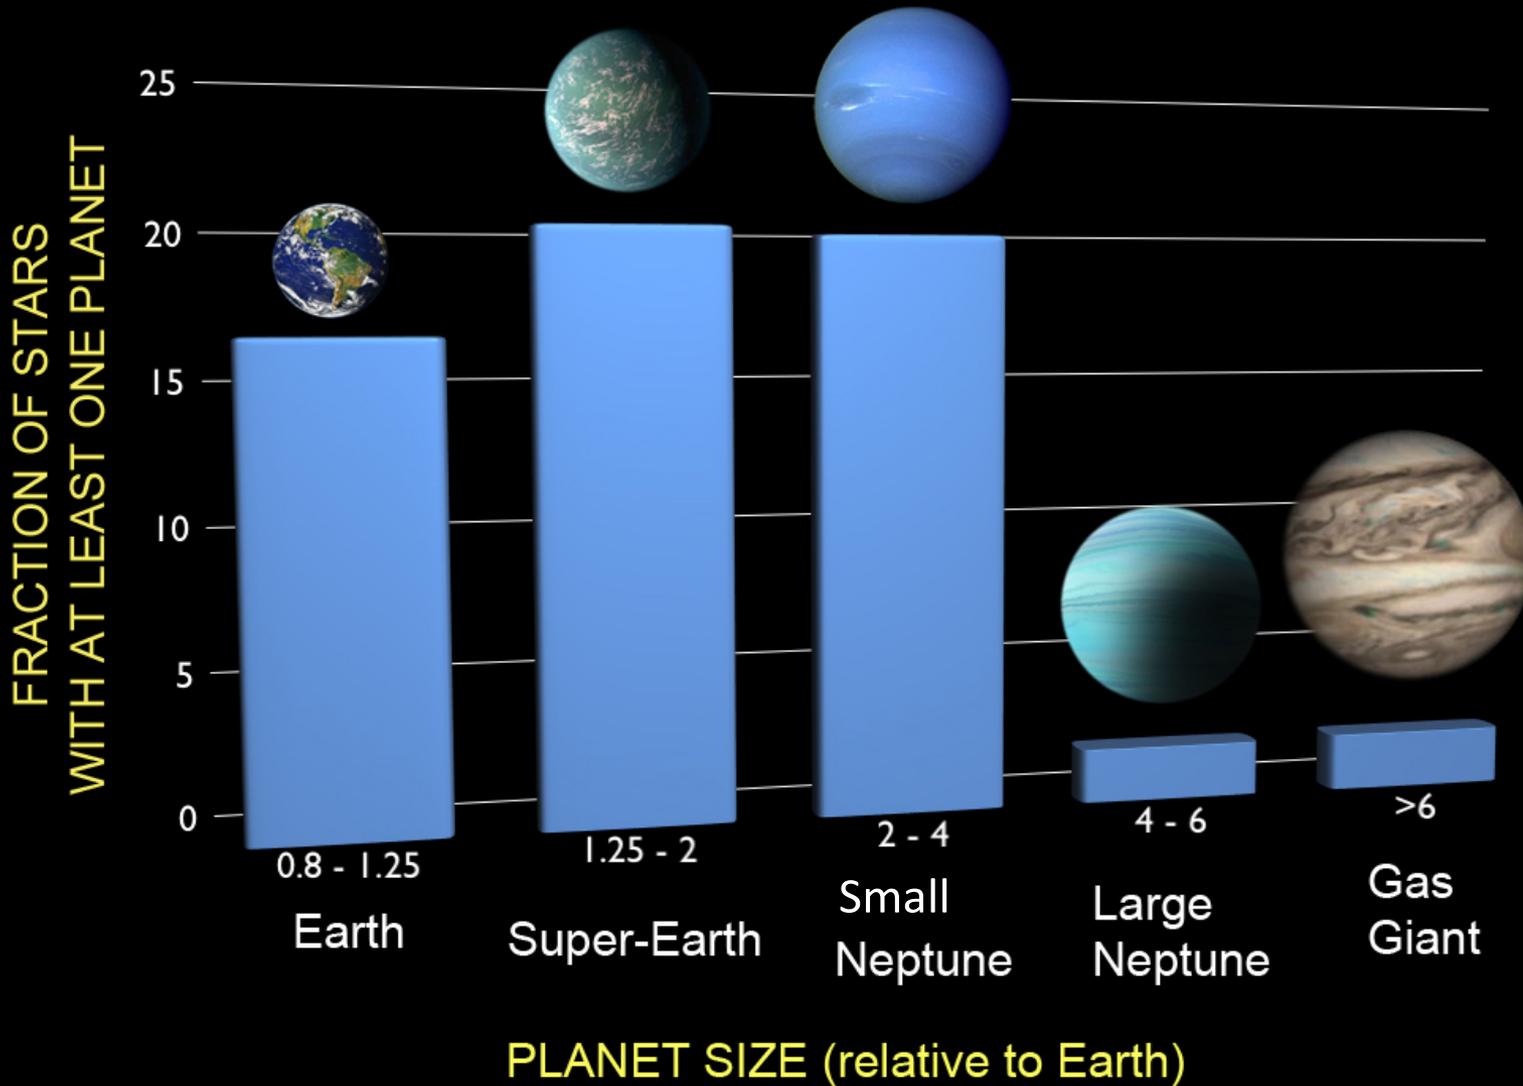

- 2,740 candidates around 2,036 stars from 22 months of data.
 - 351 are earth-size
 - 58 are in the HZ
 - 23% (467) of stars have more than one candidate
 - 10 candidates in habitable zone are less than twice the size of Earth.
 - One, now confirmed, orbits a sun-like star: Kepler-69c
 - New candidates added as they are found
 - 2810 now on observer's web site
<https://cfop.ipac.caltech.edu> and
<http://exoplanetarchive.ipac.caltech.edu/>
 - More to come soon
- 132 confirmed planets

Kepler Census - 10 July 2013

- 3,278 candidates around 2,468 stars from 36 months of data.
 - 540 are earth-size
 - 102 are in the HZ (185 to 303 K, -126 to 86 F)
 - 22% (540) of stars have more than one candidate
 - 17 candidates in habitable zone are less than twice the size of Earth.
 - One, now confirmed, orbits G type, sun-like star: Kepler-69c
 - New candidates added as they are found
 - 3278 now on observer's web site
<https://cfop.ipac.caltech.edu> and
<http://exoplanetarchive.ipac.caltech.edu/>
- 135 confirmed planets

Occurrence of Planets

Stars & Planetary Systems

17 %, 1 in 6, stars have an Earth-size planet with period less than 85 days

And 70 % have a planet of any size with period less than 400 days

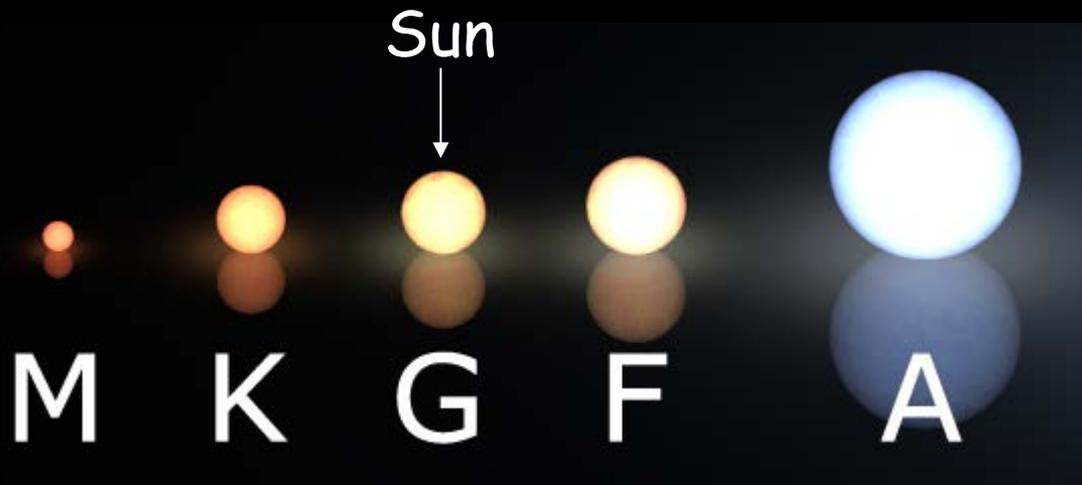

Not including long-period Earths & Super Earths

Almost all Sun-like stars have a planetary system !

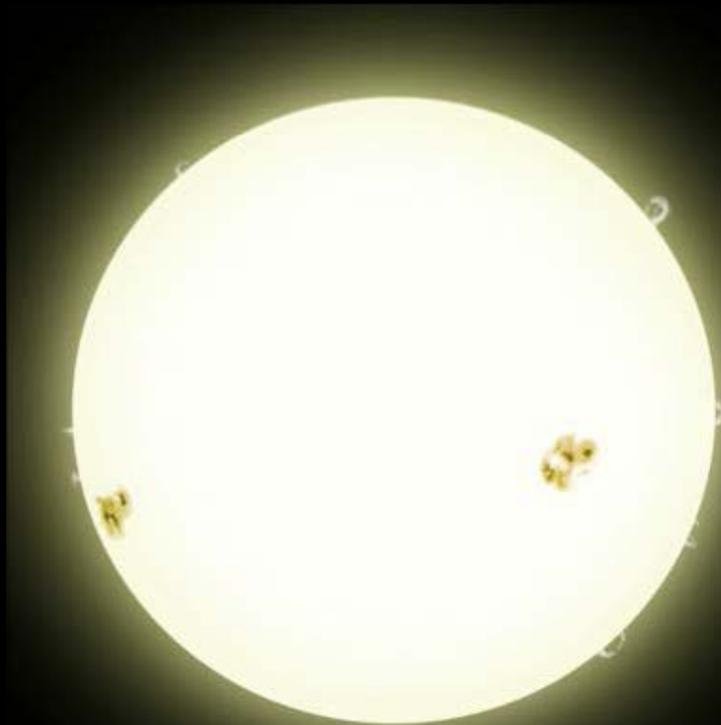

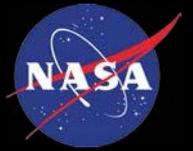

Planets and stellar type

It was previously thought that small planets were more common orbiting small stars

The results of Kepler can be explained with planets equally common orbiting the different stellar types

Stars in the Solar Neighborhood

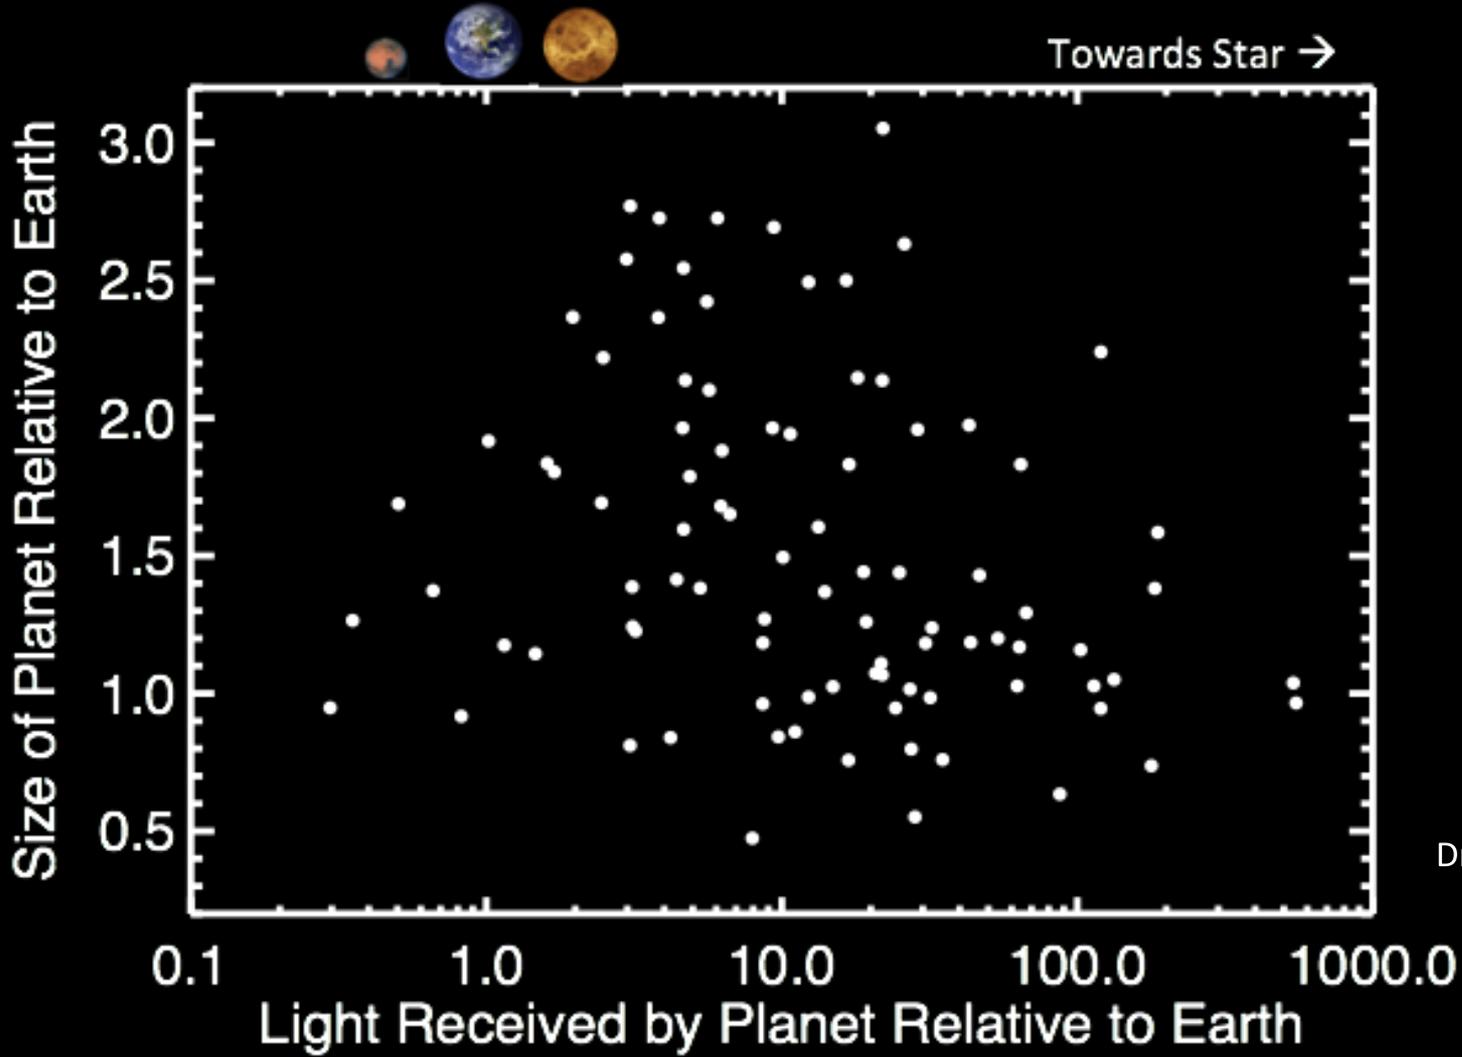

Sun G2

**Red Dwarf
M4**

25% Mass of Sun
0.2% Luminosity
10x More Common

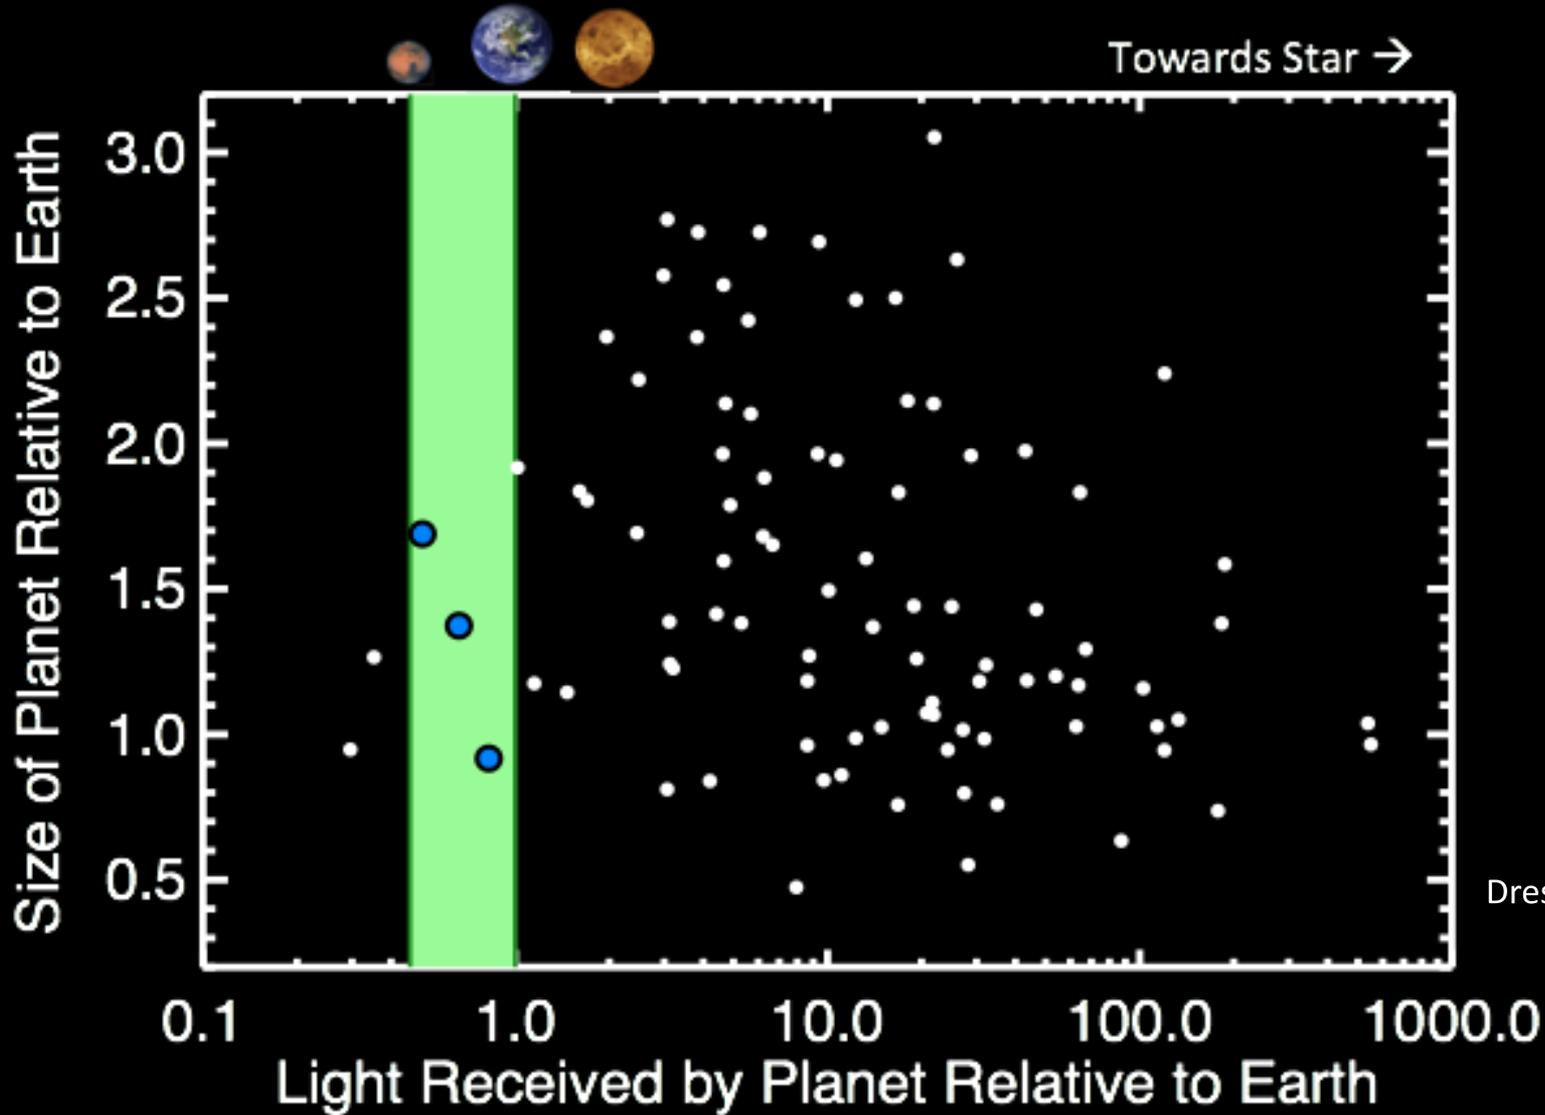

95 Planet Candidates Orbiting M-type Stars

Dressing et al

At least **60%** host a planet smaller than Neptune

3 HZ Candidates Orbiting M-type Stars

6% host planets smaller than $2.5R_e$ in the HZ

..the nearest earth-size planet in the Habitable Zone could be just a “stroll across the park,” or 13 LY.

Kepler Status

Kepler is stable and safe in Point Rest State.

Two of its four reaction wheels have failed.

Kepler cannot point with precision with less than 3 wheels. Science data collection has stopped.

Kepler must use thrusters to maintain attitude

Point Rest State is very fuel efficient.

Expect 3-4 years of fuel. We have time to think.

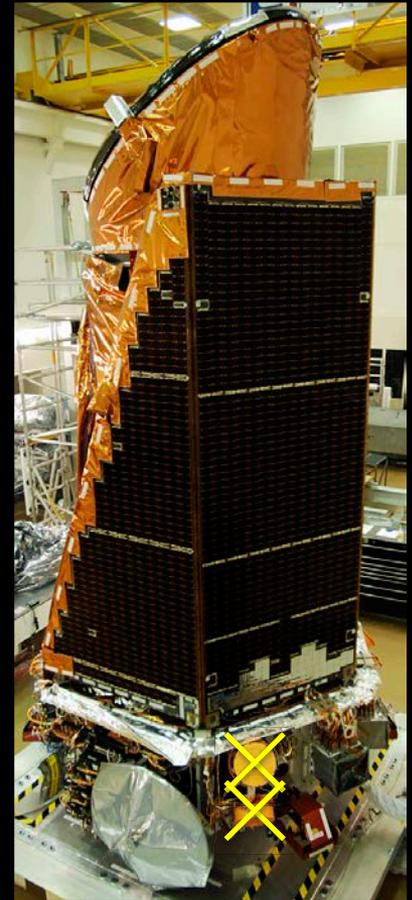

But Kepler is not dead!

All science data on the spacecraft was retrieved.

The last 2 years of data have yet to be analyzed.

This analysis will continue and we expect many more planets and much more science to come from Kepler.

The elusive Earth-analog may still lurk in the data!

Kepler Status

Kepler has three known cards to play

Try to restart recently dead wheel

Wheel spins in reverse. Still have to check forward.

Try to restart previously dead wheel

Spins but don't know about performance

A wheel restart could add some lifetime to the exoplanet survey but we would not expect the revived wheel to last long.

Try to implement a 2-wheel/thruster hybrid pointing mode

If restarts fail the hybrid pointing mode could, if it works, revive Kepler with lower precision photometry.

We would then have to decide if the science return was worth the cost.
