

A Multifaceted Approach to Modernizing NASA's Advanced Multi-Mission Operations System (AMMOS) System Architecture

Jeff A. Estefan / Brian J. Giovannoni

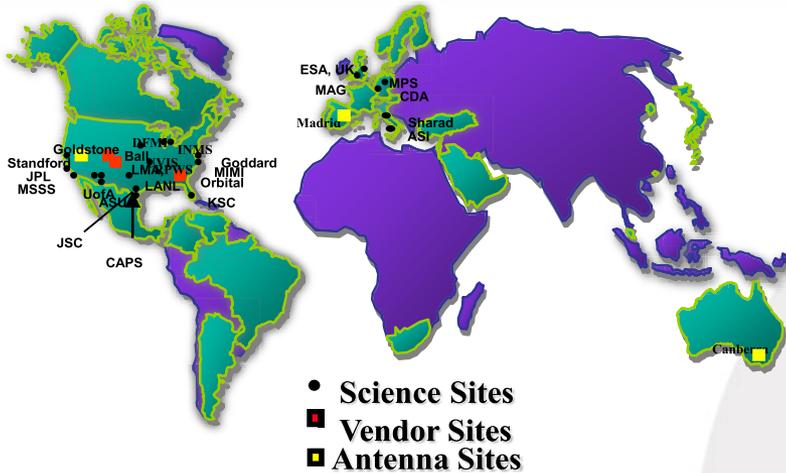

Jet Propulsion Laboratory / California Institute of Technology

SpaceOps 2014, 5-9 May 2014, Pasadena, California, U.S.A.

Agenda

- Today's AMMOS
- The Evolutionary AMMOS
- Current Challenges
- Improvement Opportunity
- Customer-Driven Architectural Goals
- Core Architectural Tenets
- Architecture Highlights
- Summary

Today's AMMOS Overview

Facilities

- Hosted on workstation-class computing platforms connected via a secure flight network supporting data interchange and interaction among the functions
- Projects can choose to obtain elements (tools and services) of their MOS from the AMMOS
 - AMMOS systems must be customized (adapted) to project specifications

Capabilities

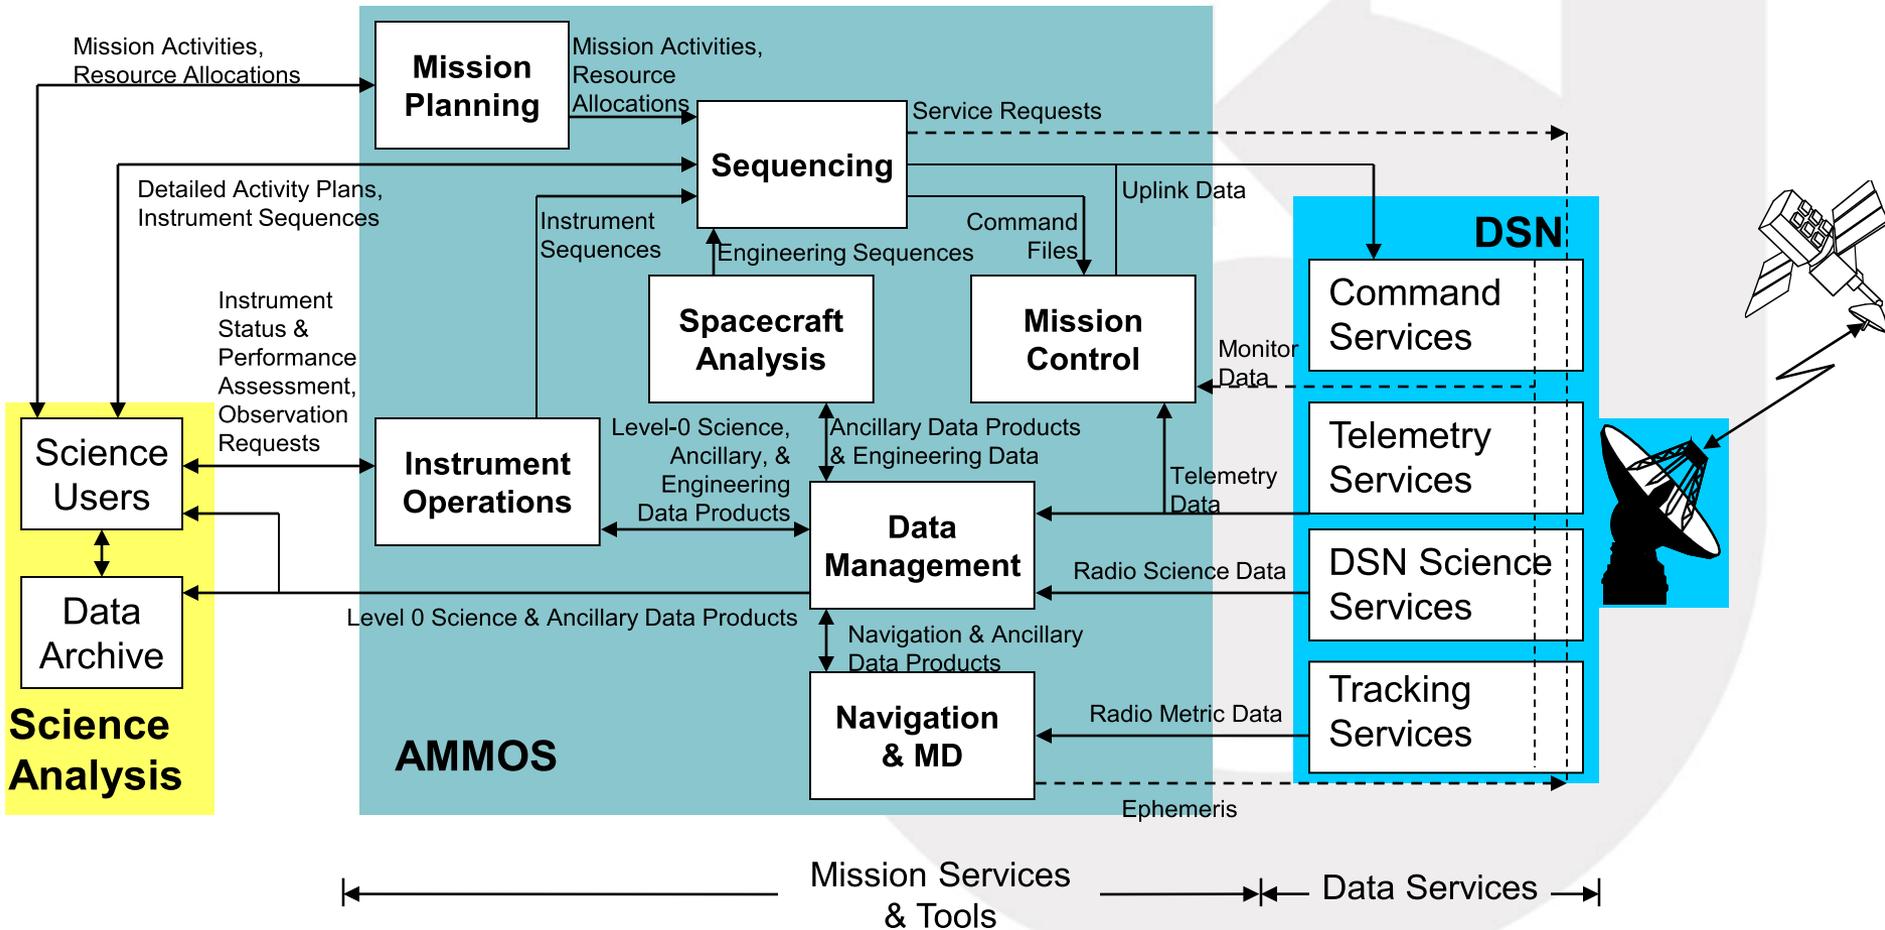

- NASA's AMMOS provides tools and services that are common to most deep space and astrophysics missions
 - Navigation & Mission Design
 - Mission Control
 - Data Management
 - Spacecraft Analysis
 - Instrument Operations
 - Mission Planning & Sequencing
 - Test Development & Operations support
 - Communications, Computers, Configuration

Business Value

- **Lowers mission cost and risk by providing mature base for project MOSs with significantly reduced development and deployment time**
- **Tailored support for a large number of diverse missions**
- **Efficient mission & science operations at globally distributed sites**
 - Collaborating communities of scientists

Today's AMMOS

Functional View (w/Major Interfaces)

The Evolutionary AMMOS

AMMOS Modernization [1]

- The AMMOS has evolved over the years and is currently a mixture of capabilities developed using older technologies and newer state-of-the-art technologies
- “Advanced” is in the name to reinforce NASA’s intent to continually invest in the AMMOS to keep pace with state-of-the-art/practice
 - Continual, modest evolution of the system was determined to be more cost effective than periodic large incremental updates
- Nevertheless, the level of new investment dropped significantly in the late 1990s and early 2000s
 - The AMMOS began to lag the existing technology
 - Projects began to notice and voice concern
- This led to the formation, in FY2005, of Multimission Ground Systems & Services (MGSS) Prgm Office with a mandate to “reinvigorate the AMMOS”
- In response, MGSS has been actively pursuing modernization and continues to evolve the AMMOS by incorporating enhanced capabilities and newer technologies into AMMOS
- Considerable progress has been made and is continuing to be made

The Evolutionary AMMOS

Approaches to Modernization [1]

- General approach has included the following categories of improvement:
 - Replacement of obsolete systems (some critical systems have a heritage from the 1960s)
 - Brings applications up to modern programming standards
 - Improves operability, testability, and maintainability
 - Remediation of dated hardware systems
 - Replaces aging and unreliable hardware (workstations, routers, switches, etc.)
 - Addition of fundamental new capabilities
 - Revitalization of multimission operations teams and processes
 - Upgrade to the technical infrastructure
 - Pro-actively extending the use and implementation of the AMMOS to a wider NASA community

Current Challenges

Flight Project Issues*

- 1. Mission information is represented in multiple instances (generally in many flat files spread across the system) and tightly coupled with software applications**
 - Difficult and inefficient to manage same piece of information in multiple formats and locations across end-to-end spacecraft activity
 - From planning to execution to receipt of downlink data and across mission activities (system development, system test, ATLO, operations, etc.)
- 2. Operating the system is more complex than desirable; should reduce need for personnel to perform manual, time-consuming work to reconcile plans with predictions and observations**
- 3. Instantiating the system and making updates to it is disruptive and causes the need to retest more software than simply the software that has been modified (and its dependencies)**
 - Instantiating a system in development environment then test environment then ATLO environment then operations environment is time-consuming and requires a lot of personnel

**List reflects synthesized set of the top issues/pain points for flight projects when standing-up their project MOSs, based on stakeholder interviews with multi-project mission operations personnel.*

Improvement Opportunity

Architecture Modernization

- **An inflection point in AMMOS modernization has been reached**
 - **Limits to evolutionary modernization model** that focuses principally on functional areas without consideration of overall system architecture
 - Substantiated by list of top flight project issues
 - Current AMMOS architecture utilizes **lowest common denominator** approach to integrating GSW applications across functional areas
 - File Transfer w/pipe-and-filter connections (in use since AMMOS inception)
 - Approach necessary many years ago when standards, technologies, and best practices to application integration were limited – **Not the case today**
 - **No common runtime platform provisioning model**, prescriptive set of industry standards, or third-party software used across *all* AMMOS functional areas
 - **A better integrated, “Family of Systems” approach** is needed to help drive down cost of standing up a Project MOS
 - Lower the cost of tool and mission service integration
 - Leverage economies of scope in use of common standards, technologies, and platform computing capabilities for AMMOS core assets

Customer-Driven Architectural Goals*

Mapped to Flight Project Issues

Issue*	Goal
Multiple instances of mission data tightly coupled with software applications	Lower the cost of integration across AMMOS functional areas
Difficult to reconcile plans with observations	Increase operations efficiency in multimission operations while reducing risk and enhancing mission return
Instantiating, testing, and maintaining system is difficult	Improve ability to test, deploy, and maintain the AMMOS in mission environments‡

‡Parallel Goal: Lower the cost and effort to the program to test, deploy, and maintain the AMMOS

**Oriented toward mission customer/flight project needs. There also exists a set of System Strategic Goals articulated in the NASA AMMOS Strategic Plan & Roadmap (summarized in the Backup slides). The new architecture needs to respond to both.*

Core Architectural Tenets [2]

Foundational Concepts

1. ***Timeline as the Foundational Data Structure of our Domain***

- “Timeline” proposed as basis of unifying ‘canonical’ (common/standardized) information model for storage and communication of MOS time-varying information (by functional software applications *and* in operations)
 - Help reduce adaptation cost by lowering cost of integration
 - Serve as basis for end-to-end data accountability

2. ***MOS as a Closed-Loop Control System***

- Envision closed-loop control system tasked with achievement of mission and science goals, managing resources, and capable of closing the loop on goals and resource management “out-of-the-box”
 - Help increase operations efficiency (fewer gaps in operations processes that must be closed by costly and inefficient means)

3. ***Institutionalizing the Practice of Separation of Concerns (SoC)***

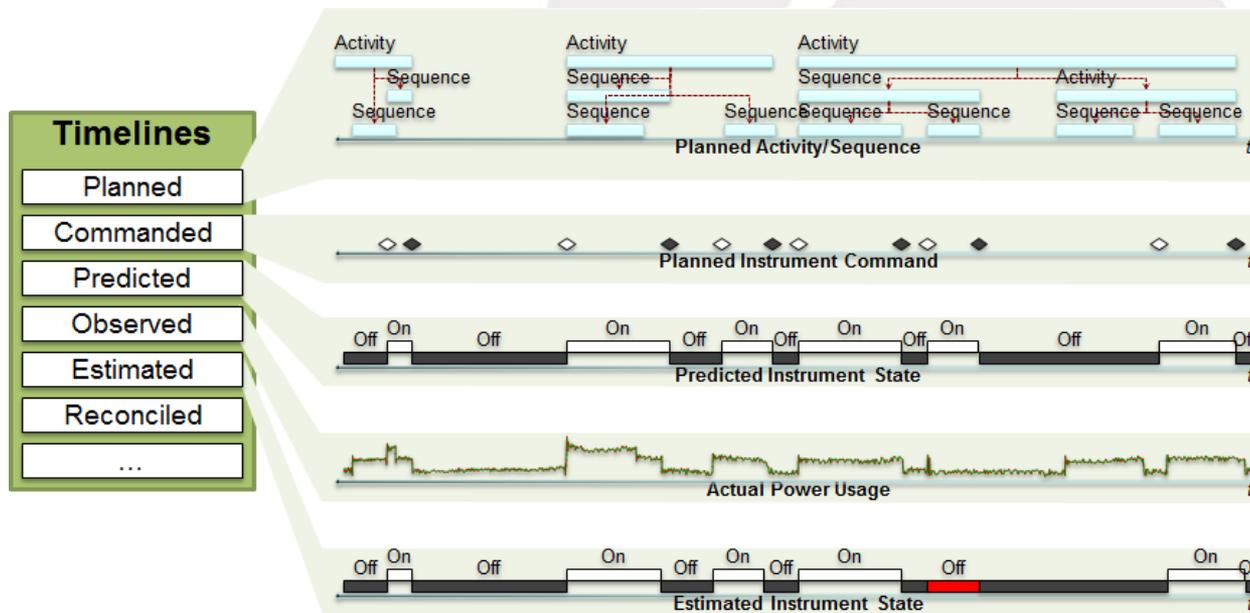

- Apply architectural pattern of “layering” providing logical separation of functions with each layer having specified set of roles and responsibilities
 - Help make overall system easier to deploy and maintain

Core Architectural Tenets

Uniform Information Representation – “Timelines”

Tenet 1 – *Timelines as the foundational data structure of our domain*

- A **timeline** is a representation of time-varying information; more specifically, a set of a set of values with associated times
- Example timelines for representing time-varying MOS information:

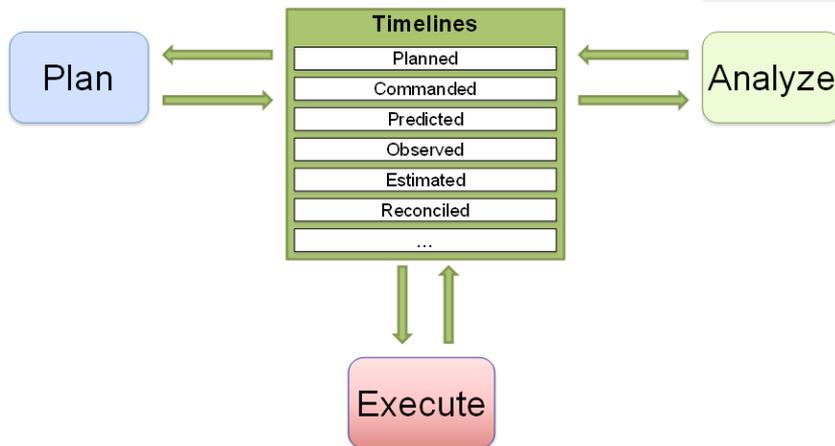

Core Architectural Tenets

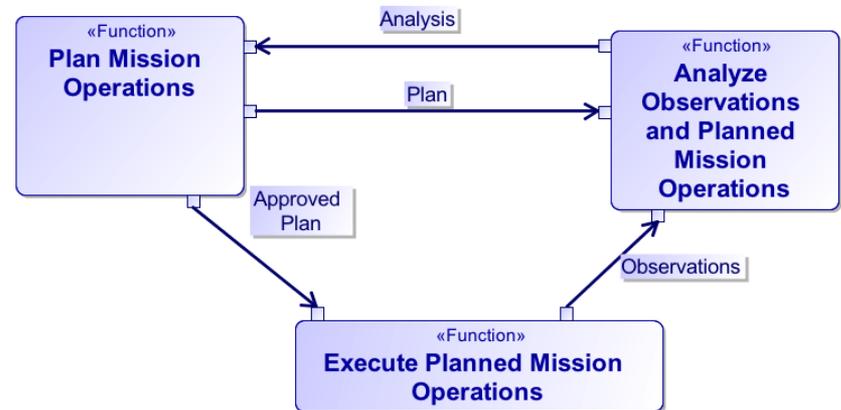

[Timeline-Centric] Closed-Loop Control Pattern

Tenet 2 – *MOS as a closed-loop control system*

- Plan, Execute, Analyze (“PEA”) closed-loop control pattern centered around Timelines

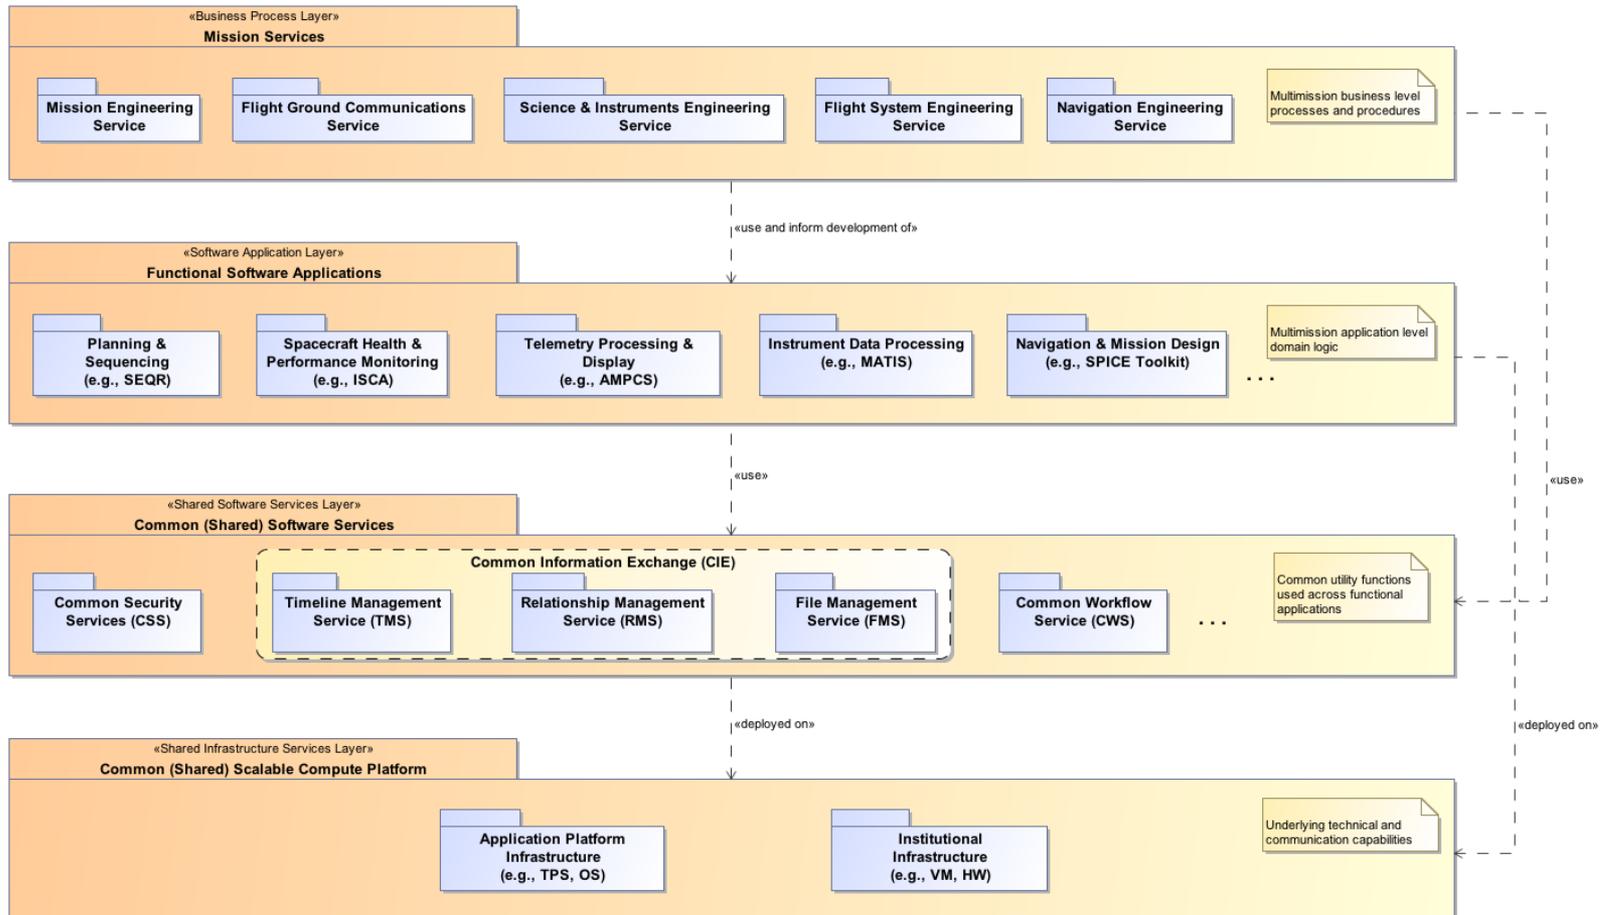

- Allows missions to standardize planning, execution, and reconciliation operational processes

Core Architectural Tenets

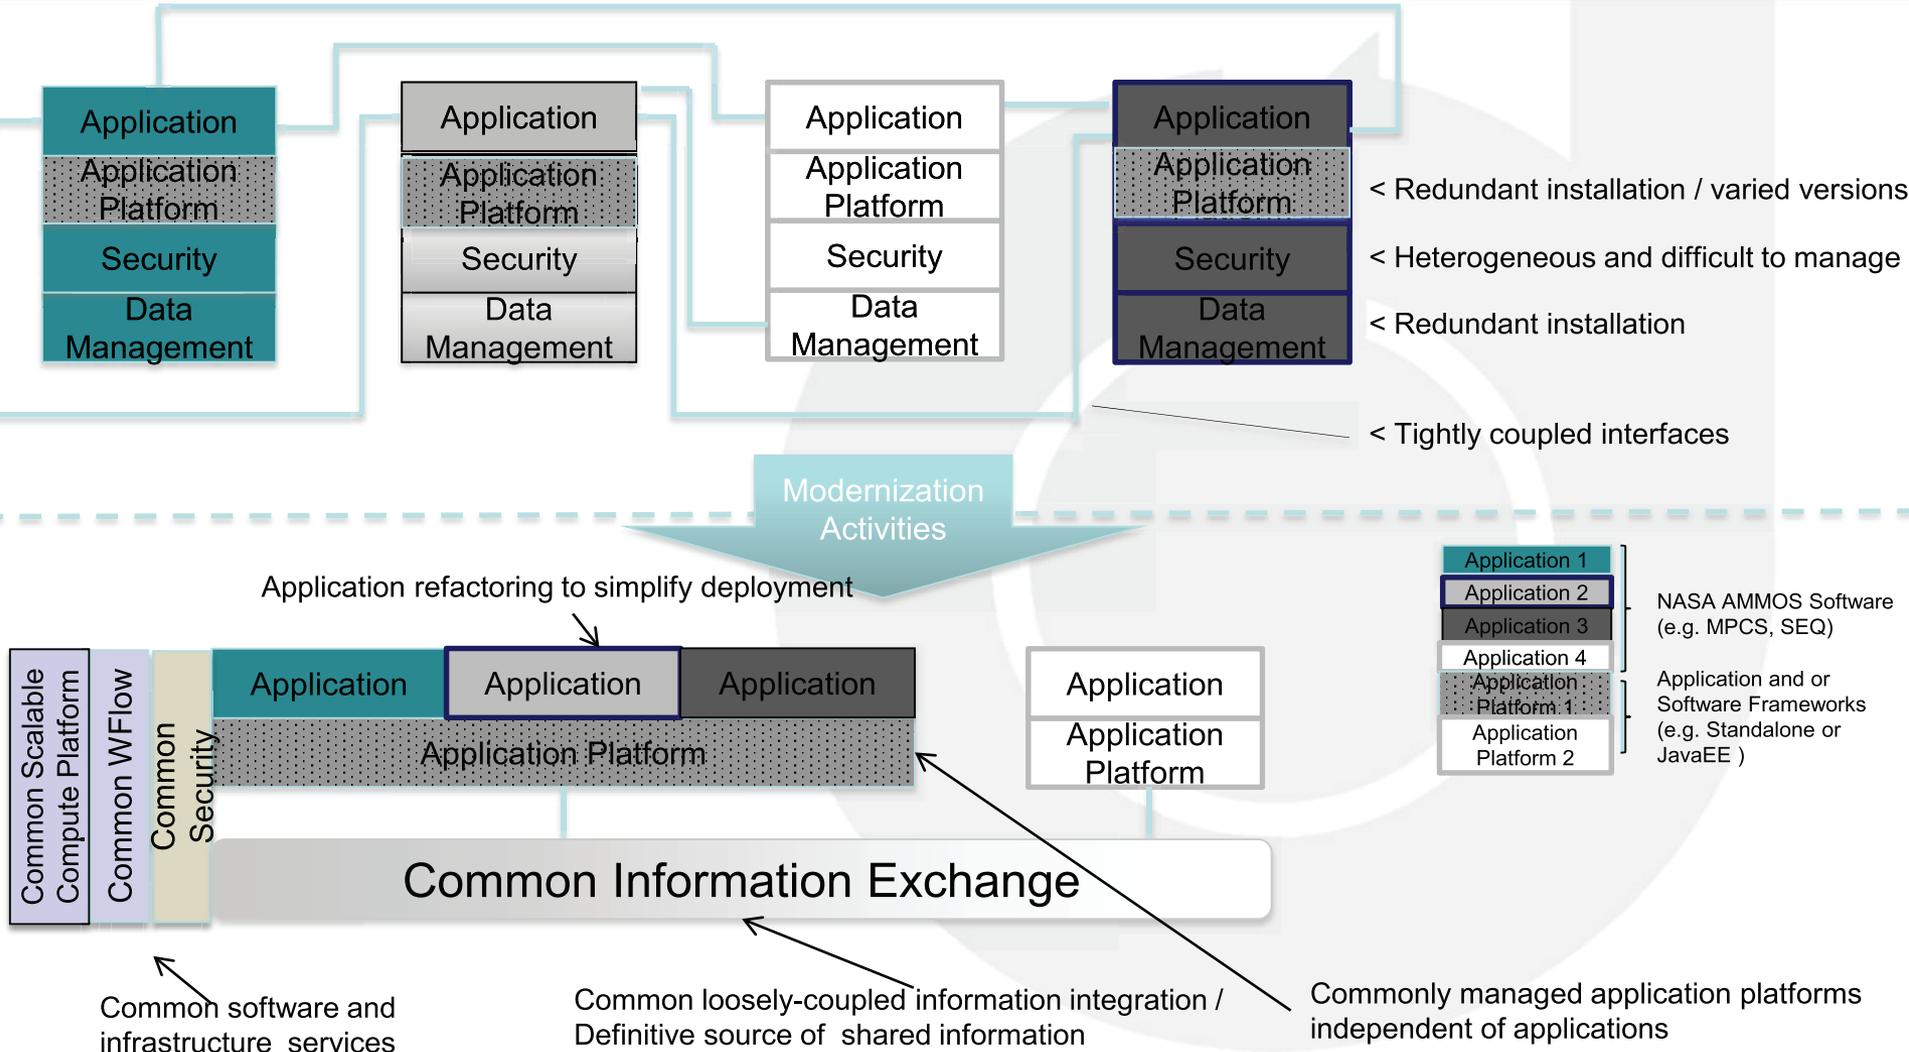

Architectural Layering

Tenet 3 – Institutionalizing the practice of Separation of Concerns (SoC)

Architecture Highlights

Multimission GDS Modernization

Summary

How the New Architecture Responds to Flight Project Issues

Issue	Response
Multiple instances of mission data tightly coupled with software applications	<ul style="list-style-type: none"> • Timelines and other definitive sources of MOS information managed by Common Information Exchange set of services
Difficult to reconcile plans with observations	<ul style="list-style-type: none"> • [See 1st bullet above] • Operations modernization allows missions to standardize planning, execution, & reconciliation operational processes
Instantiating, testing, and maintaining system is difficult	<ul style="list-style-type: none"> • Commonly managed, application-independent platforms

Architecture Highlights

Evolvable Application Integration Strategy

AMMOS System Strategic Goals [3]

Lower Cost / Risk for Mission Ops

Goal #1 AMMOS will continue to evolve and improve its tools and services to reduce Mission Operations cost and risk

Improve Infrastructure

Goal #2 AMMOS will evolve its infrastructure to be consistent with appropriate technological advances in emerging standards, computing, and architecture

Support Future Missions

Goal #3 Broaden AMMOS to support future missions

Capitalize on future SCan architecture

Goal #4 AMMOS is compatible with future changes to Space and Ground Communications Infrastructure

Strategic Goals

The World's Forum for Aerospace Leadership
