

# **Trending Main Engine Assembly (MEA) Cover Actuator Performance using Cassini Attitude Control Flight Data**

**Luis G. Andrade Jr.**

**Cassini Spacecraft Operations Office  
Jet Propulsion Laboratory  
California Institute of Technology**

January 8, 2016

## Objective of Study

- The Cassini S/C has an actuation mechanism that opens/closes an accordion-like cover that protects the MEA from **space/orbital debris**
- Original 20 cycle in-flight life span has now surpassed 80 cycles
- Primary plan is to use MEA cover for dust hazard protection until the end of mission in Sept. 2017 (Proximal Orbits)
- This study is the first to use Cassini **attitude control flight data** in an attempt to trend MEA cover actuator performance
- The goal is to detect any **sudden** change in cover actuation behavior that can be an early sign of oncoming actuator failure

1 cycle = 1 *deploy(close)* + 1  
*stow(open)*

Fig. 1: Flight MEA cover on Cassini before launch<sup>1</sup>

# Challenges of Study

- An inability to directly measure actuator torque output
  - Solution: Calculate “disturbance” torque imparted on S/C during cover actuations as an indirect method of trending cover actuator torque
- An unknown “true” disturbance torque profile
  - Solution: Use two different reconstruction methods to estimate disturbance torque
- A sparsity of available flight data
  - Solution: Apply smoothing and interpolating techniques to Attitude Control Subsystem (ACS) flight data

# Cassini Spacecraft

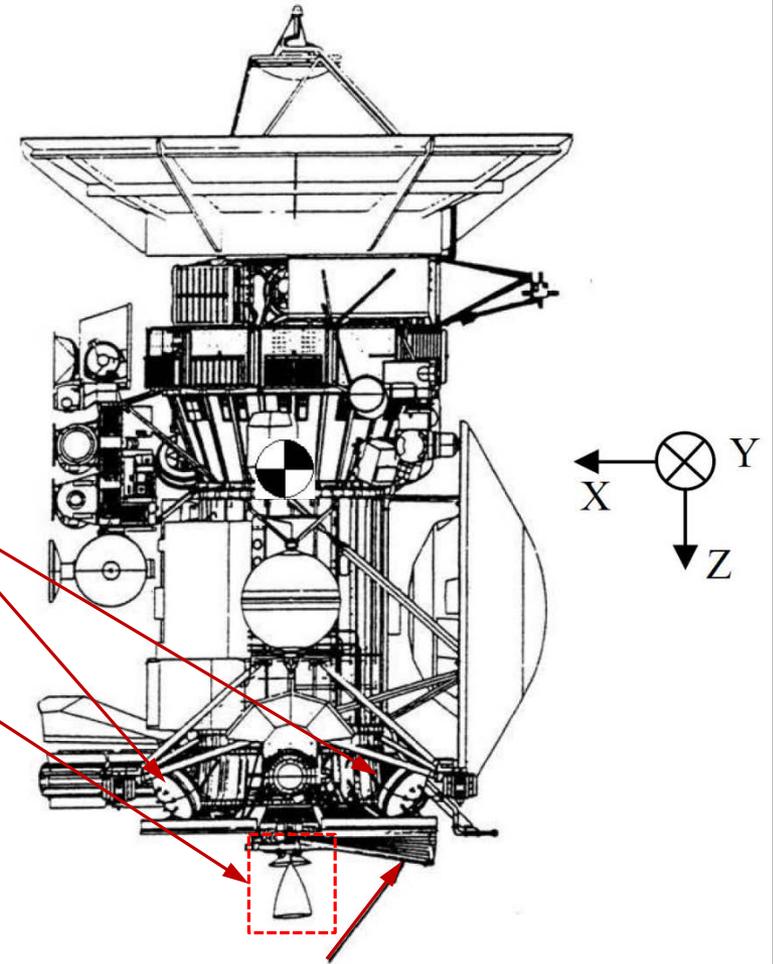

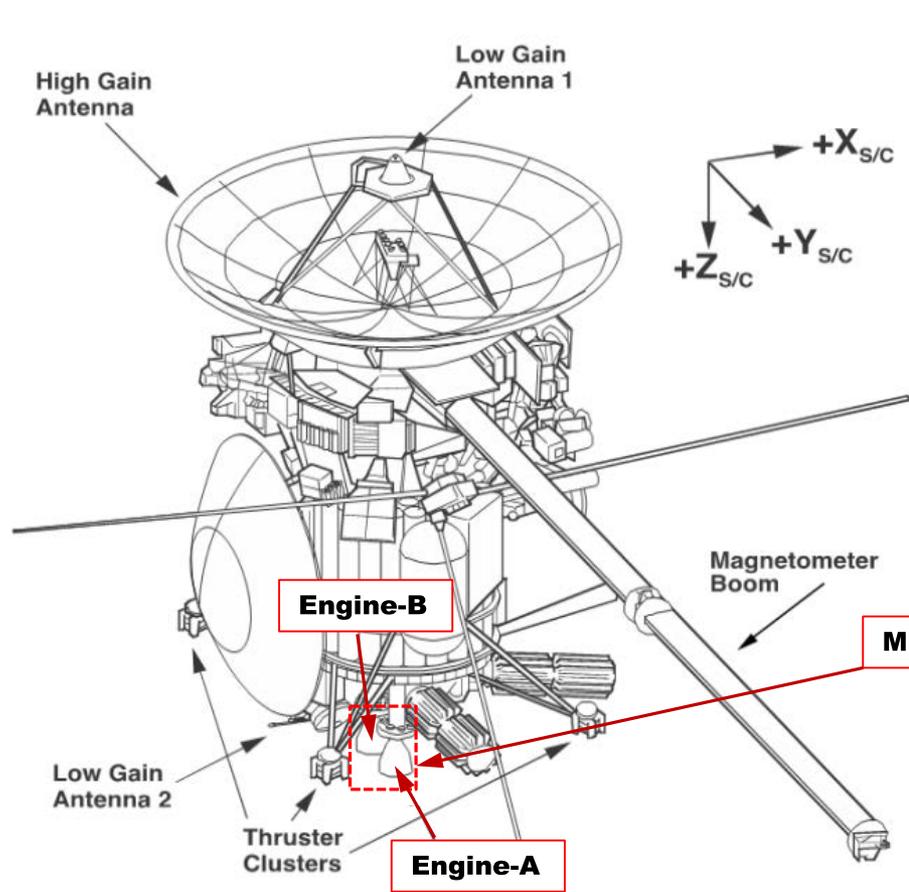

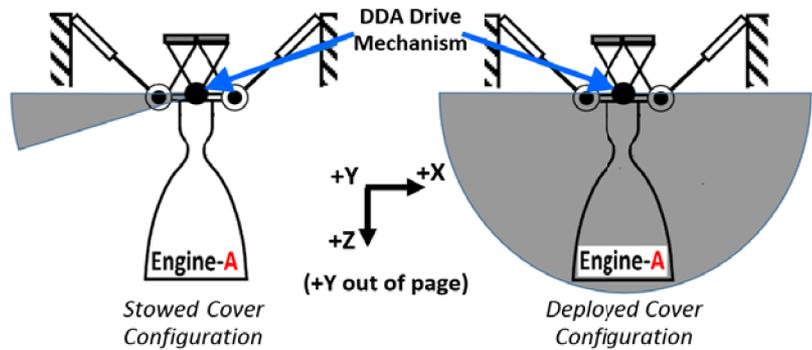

Fig. 2: Overview of Cassini S/C<sup>1</sup>

MEA cover in stowed position

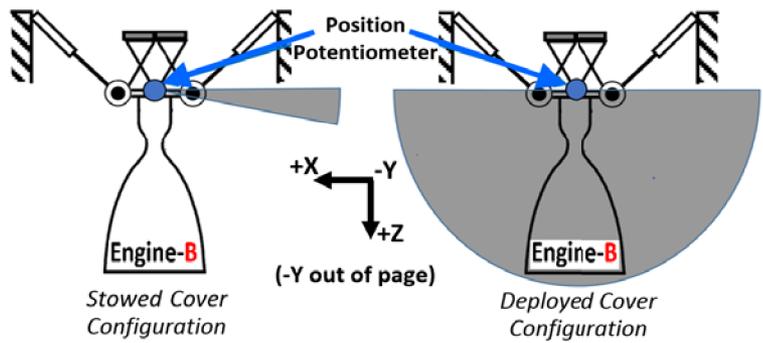

Fig. 3: Location of MEA cover on Cassini<sup>1</sup>

# MEA Cover and Actuator System

- Dual drive actuator (DDA) is composed of *two* brushless DC motors, motor-A and motor-B, but only motor-A has been used for actuations. Only motor-A is trended.

a) MEA cover stow/deploy configuration looking along -Y axis

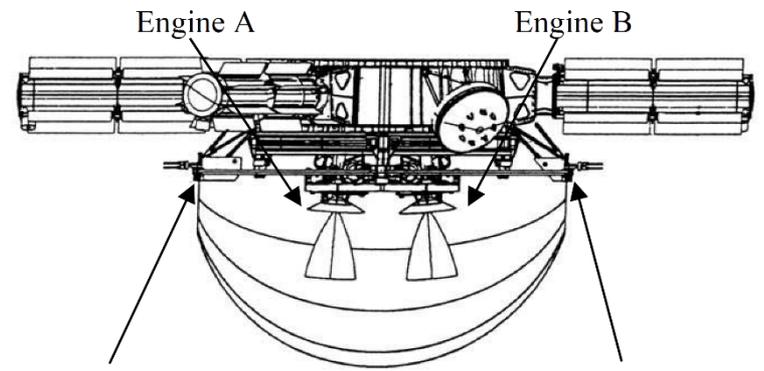

b) MEA cover stow/deploy configuration looking along +Y axis

Fig. 6: DDA and potentiometer locations<sup>1</sup>

# Two ACS Methods for Estimating Torque

- ACS has two **different** methods of estimating the **disturbance torque** imposed on the S/C by the **motion of the MEA cover**

1. Torque from Conservation of Angular Momentum (RWA rate telemetry)

$$T_{Hrwa}(t)$$

2. Torque from Transfer Function (position error telemetry)

$$T_{TF}(t)$$

- Both torque estimation methods should agree with one another in terms of the torque signature each outputs

- Can ground simulations verify results from telemetry?

# Torque from Conservation of Angular Momentum

1. Use RWA rate data to construct accumulated angular momentum
2. Smooth accumulated angular momentum
3. Take 1<sup>st</sup> time derivative of momentum to get torque
  - Assume that the accumulation in S/C angular momentum during MEA cover deployments comes *entirely* from the change in RWA rates during MEA cover deployment
  - RWA rate at the end of deployment is same as in beginning

# Torque from Conservation of Angular Momentum

- Steps in method
  1. Use RWA rate data to construct angular momentum
  2. Smooth angular momentum
  3. Take 1<sup>st</sup> time derivative of momentum to get torque
- RWA rate is same at the beginning/end of deployment
- S/C angular momentum during MEA cover deployments is **entirely absorbed** by RWAs during MEA cover deployment

S/C  
commanded  
to inertially  
fixed attitude

$$\vec{H}_{Total} = \vec{H}_{RWA} + \vec{H}_{SC}$$

$$\vec{H}_{Total} \approx \vec{H}_{RWA}$$

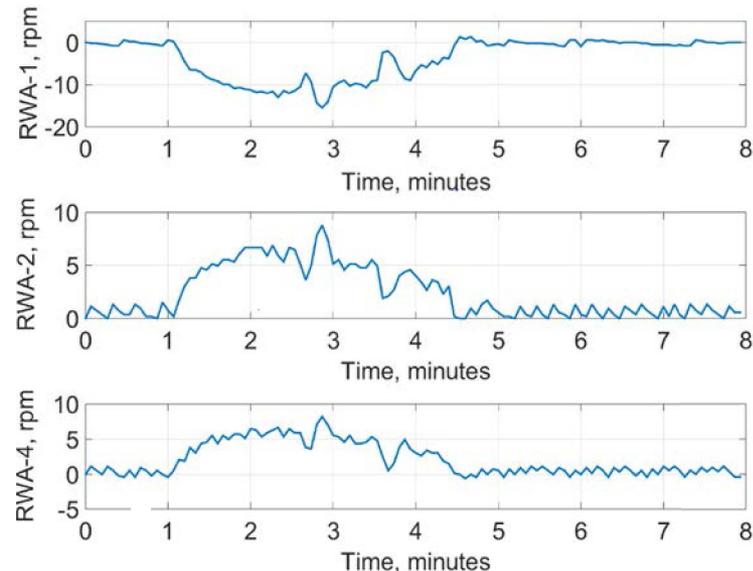

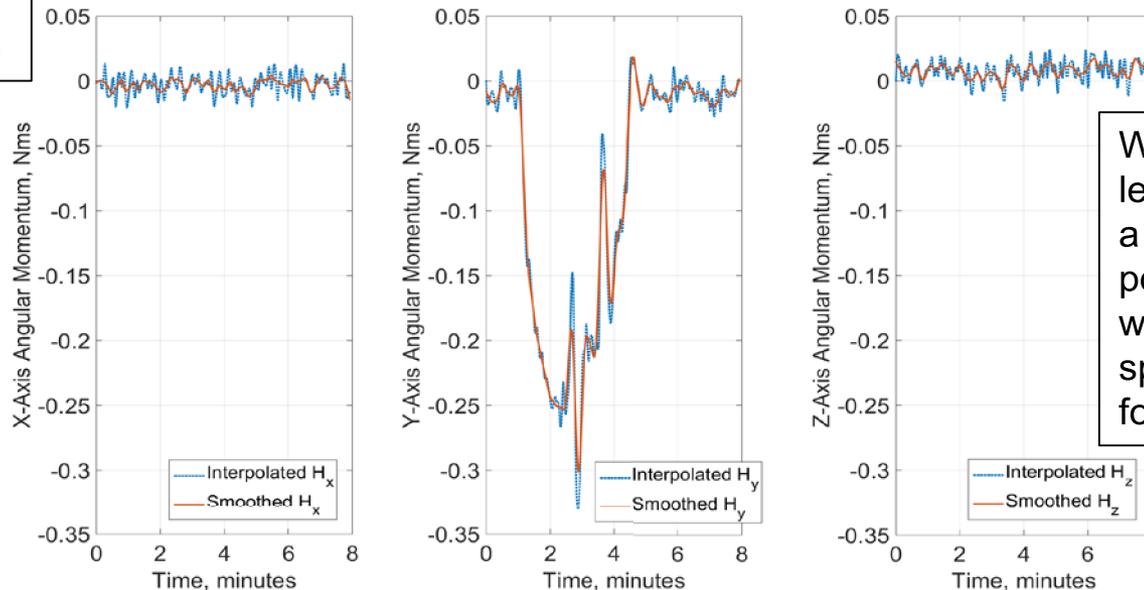

Fig. 7: RWA rate flight data<sup>1</sup>

# Torque from Conservation of Angular Momentum

$$\vec{H}_{rwa} = T I_{RWA} \vec{\rho} = \begin{bmatrix} 0 & -\frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} \\ \sqrt{\frac{2}{3}} & -\frac{1}{\sqrt{6}} & -\frac{1}{\sqrt{6}} \\ \frac{1}{\sqrt{3}} & \frac{1}{\sqrt{3}} & \frac{1}{\sqrt{3}} \end{bmatrix} \begin{bmatrix} I_{RWA-1} & 0 & 0 \\ 0 & I_{RWA-2} & 0 \\ 0 & 0 & I_{RWA-4} \end{bmatrix} \begin{bmatrix} \rho_{rwa-1} \\ \rho_{rwa-2} \\ \rho_{rwa-4} \end{bmatrix}$$

- This is accumulated angular momentum imparted on S/C by motion of cover
- Angular momentum changes only about Y-Axis as expected

Net accumulated momentum is zero

Weighted linear least squares and a 2<sup>nd</sup> degree polynomial model with a sample span of 8% used for smoothing

Fig. 8: Smoothed angular momentum<sup>1</sup>

# Torque from Conservation of Angular Momentum

- The disturbance torque imparted on the S/C by the motion of the MEA cover is

$$T_{H_{rwa}}(t) = T_{totaly}(t) = \frac{dH_{totaly}}{dt}$$

- This torque signature comes from RWA data during cover deployment
- Potentiometer/current data sheds insight into characteristics of MEA cover actuations
- Data sampled once every 64 seconds

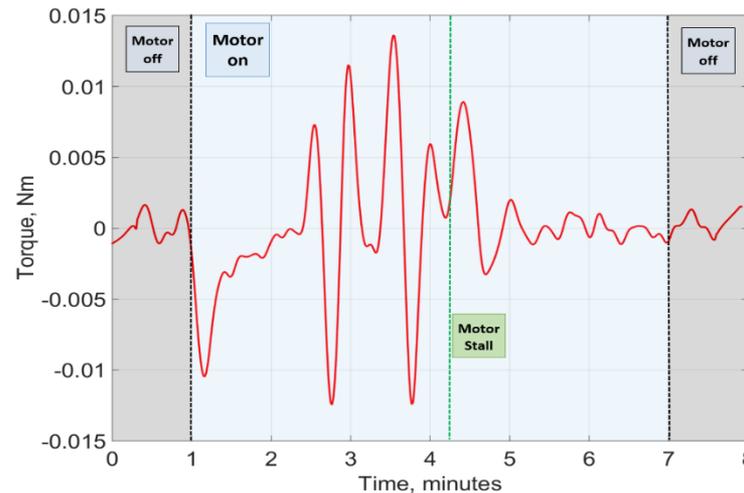

Fig. 9: Disturbance torque during MEA cover deploy<sup>1</sup>

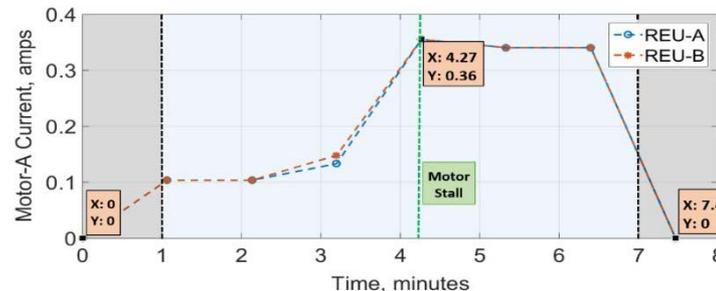

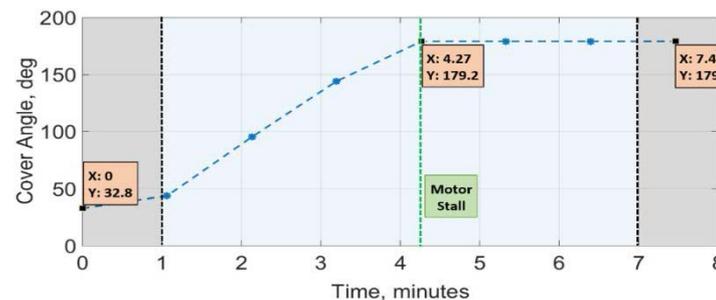

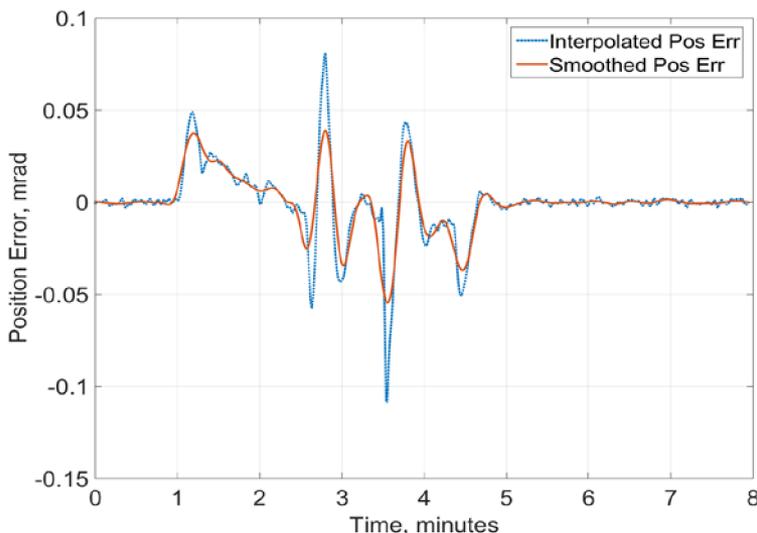

Fig. 10: Motor-A Thermal/Devices data<sup>1</sup>

# Torque from Transfer Function

- The Cassini team has previously done work to develop a transfer function of “position error to disturbance torque” for Enceladus plume torque estimates. *See full paper for details and references\**
- Based on a simplified model of the RWA Control System*

$$T_{D_y}(t) \approx -I_{YY} \left\{ \ddot{e}_{\theta_y}(t) + 0.15548 \dot{e}_{\theta_y}(t) + 0.03529 e_{\theta_y}(t) \right\} \text{ Nm}$$

$$T_{TF}(t) = T_{D_y}(t)$$

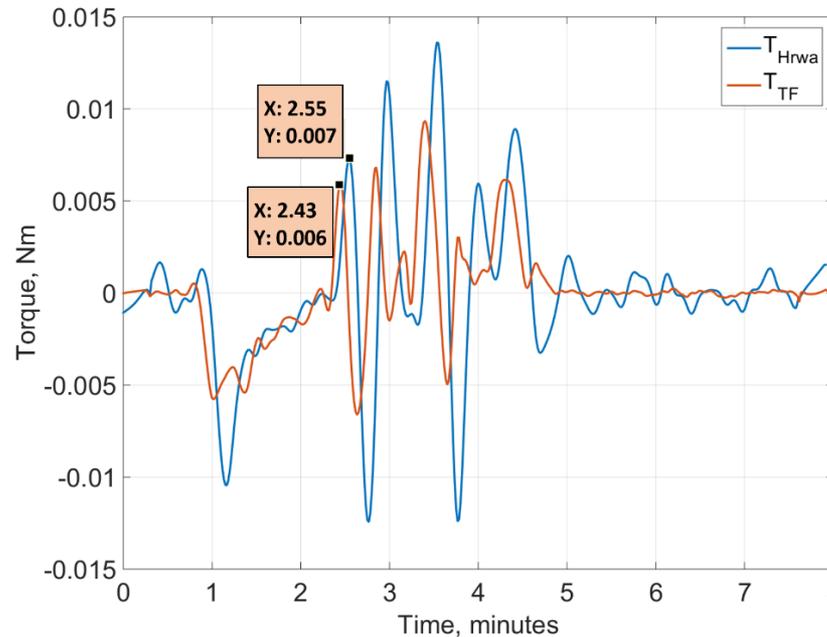

- Where  $e_{\theta_y}(t)$  is the attitude control (position) error
- Same* smoothing technique is applied to *both* ACS reconstruction methods

**Fig. 11: Smoothed Y-Axis Attitude Control Error<sup>1</sup>**

# Torque from Transfer Function

*\*Applying the same smoothing technique (8% sample span) to both reconstruction methods causes differences in magnitudes*

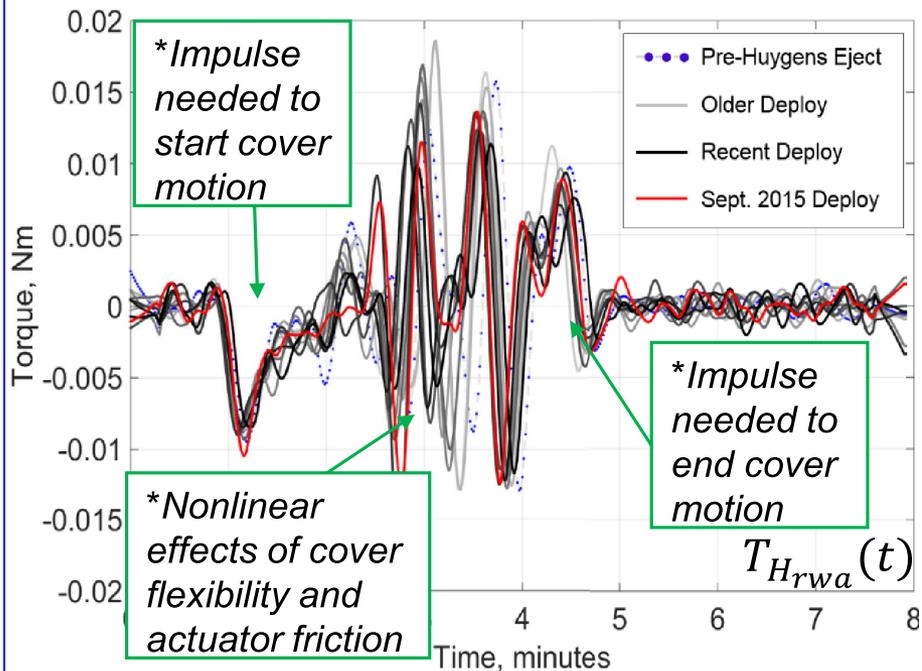

*\*RWA controller response lag causes time shift between two reconstructed torques*

**Fig. 12: Comparison of motor-A imparted disturbance torque from two reconstruction methods<sup>1</sup>**

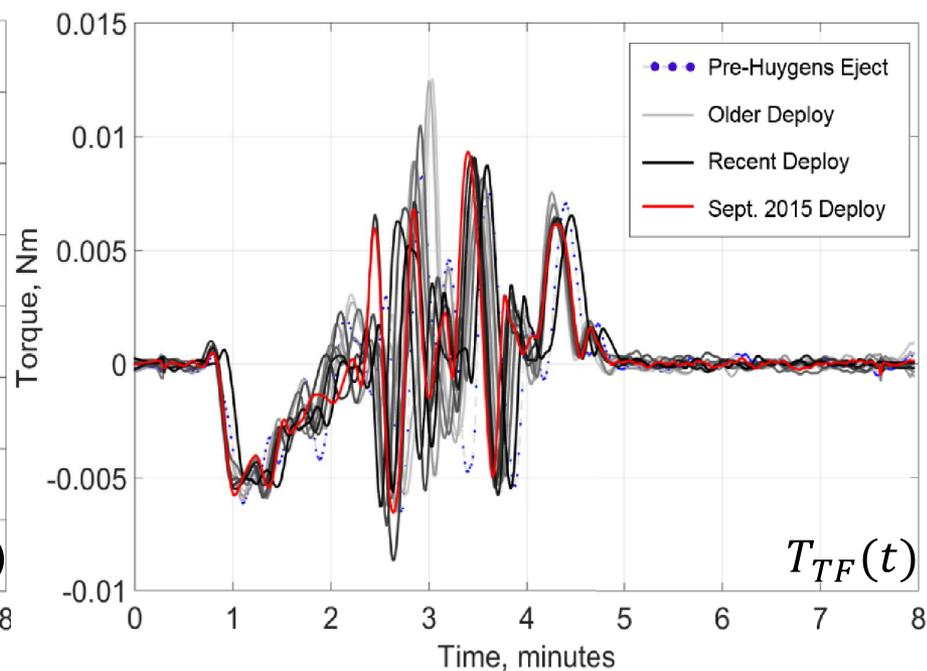

- Overall, the disturbance torque signature obtained from the “conservation of angular momentum” method,  $T_{Hrwa}$ , agrees with the signature obtained from “transfer function” method,  $T_{TF}$ .

# Trending Analysis Results (2004-2015)

- The two reconstruction methods were applied to 11 MEA cover deployments, to create trend plots of disturbance torque profiles. *MEA cover deployments listed in paper\**

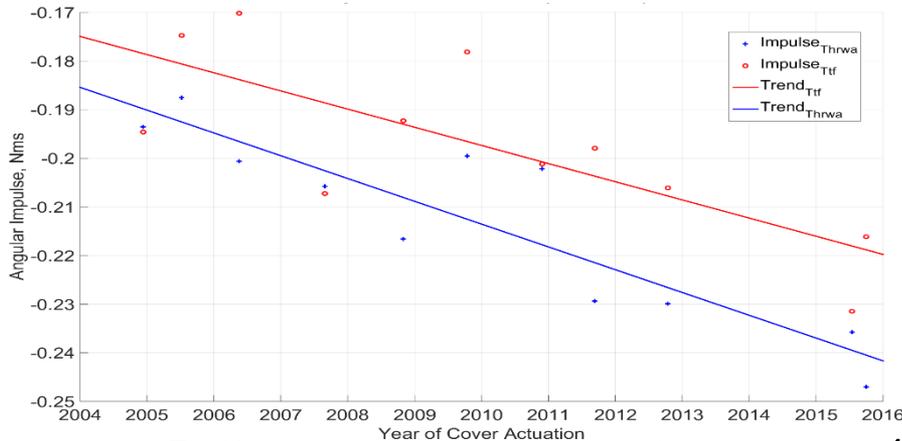

**Fig. 13: Trending plot of motor-A disturbance torque derived from Y-Axis RWA momentum<sup>1</sup>**

**Fig. 14: Trending plot of motor-A disturbance torque derived from Y-Axis position error<sup>1</sup>**

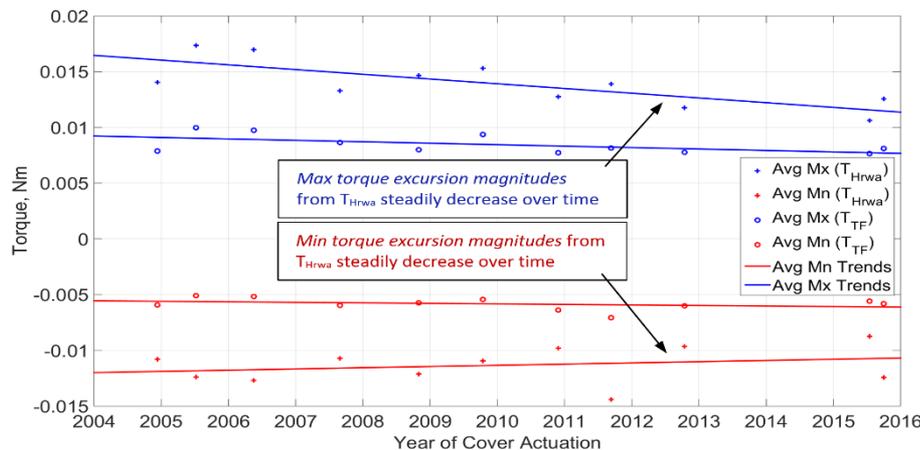

# Trending Analysis Results (2004-2015)

- Analysis done to quantify gradual change in initial impulse and in magnitudes of peak torque excursions

**Fig. 15: Gradual change in initial impulse<sup>1</sup>**

*\*Calculating the area under the Torque v. Time plots reveals that impulse magnitude increases by ~30% from 2004-2015*

**Fig. 16: Gradual change in peak torque excursions<sup>1</sup>**

*\*Calculating the average of the two min and two max torque excursions in the Torque v. Time plots reveals that these spikes are decreasing in magnitude by ~33% from 2004-2015*

# Two ACS Methods for Estimating Torque

- ACS has two **different** methods of estimating the **disturbance torque** imposed on the S/C by the **motion of the MEA cover**

- Torque from Conservation of Angular Momentum (RWA rate telemetry)

$$T_{H_{rwa}}(t)$$

- Torque from Transfer Function (position error telemetry)

$$T_{TF}(t)$$

- Both torque estimation methods should agree with one another in terms of the torque signature each outputs

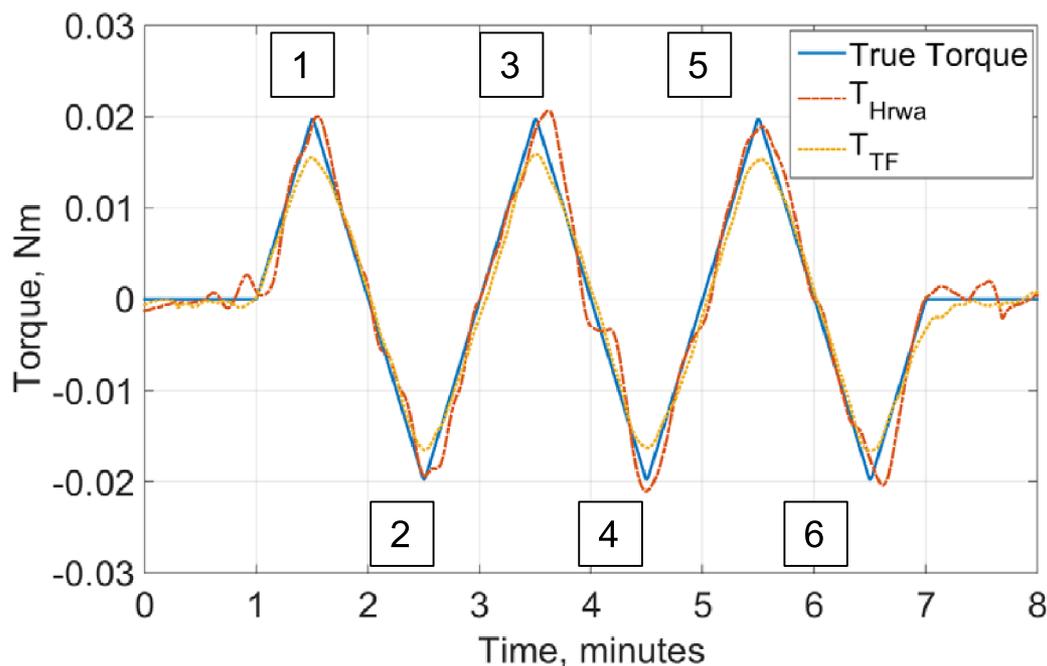

- Can ground simulations verify results from telemetry?

# Ground Simulation Verification

- Flight Software Dynamic Simulation (FSDS) – high fidelity simulation environment with full environmental dynamics and the Cassini flight software (FSW) built in
- Inject a *known* torque profile into FSDS and try to reconstruct it from simulated flight data

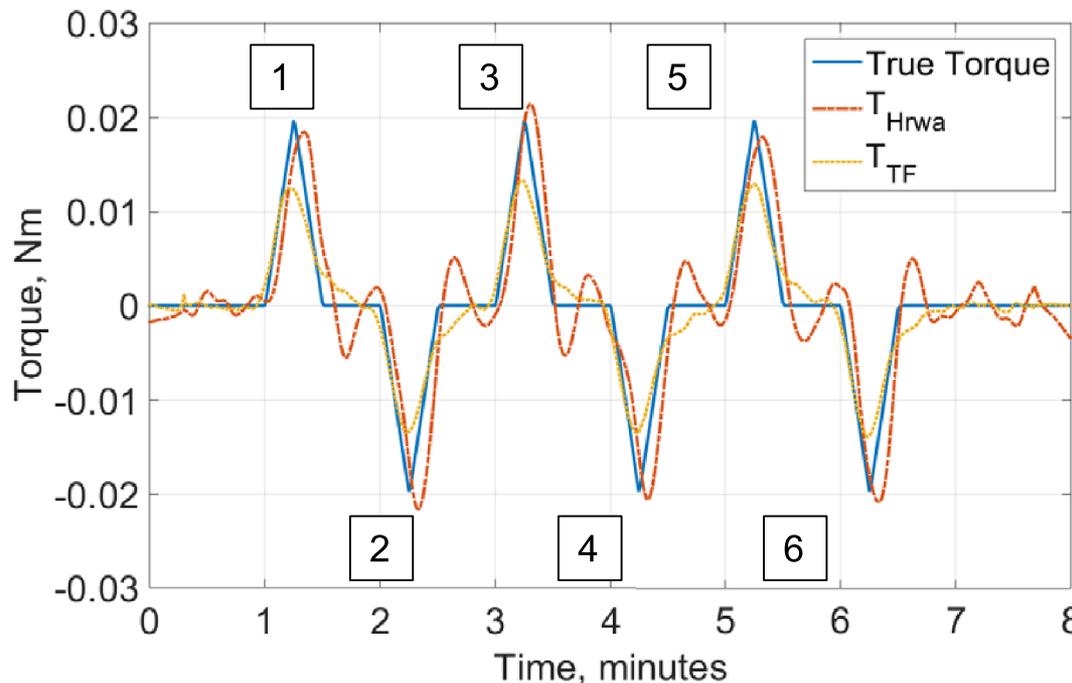

Max Peak Error = 5.97% at peak #4

**Fig. 17: Comparison of reconstructed torques to FSDS-injected torque profile #1<sup>1</sup>**

# Ground Simulation Verification

- Inject a second *known* torque profile into FSDS and try to reconstruct it from simulated flight data

Max Peak Error = 9.91% at peak #2

Fig. 18: Comparison of reconstructed torques to FSDS-injected torque profile #2<sup>1</sup>

# Conclusion

- Cassini ACS team used *two different* disturbance torque reconstruction methods to trend MEA cover deployments from **2004 to 2015**, using real flight data
- Qualitative and quantitative trending analysis showed consistent behavior across the years, with **no sudden changes in torque signature** that may indicate failure in the MEA cover mechanism before 2017
- FSDS ground simulations were used to verify the torque reconstruction procedures and find an upper bound to the max peak error ( $\sim 10\%$ )
