3 Modeling studies

Need for brown dwarf (BD) modeling

(de Kok et al. 2011)

- Polarimetry makes BD measurements sensitive to asymmetric features like oblateness and patchy clouds

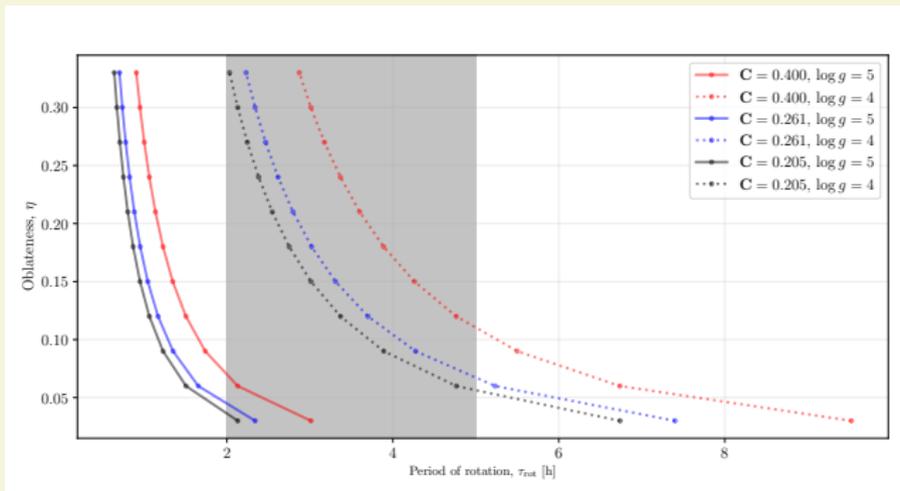

Need for brown dwarf (BD) modeling: oblateness

(Herbst et al., Scholz & Eislöffel 2004)

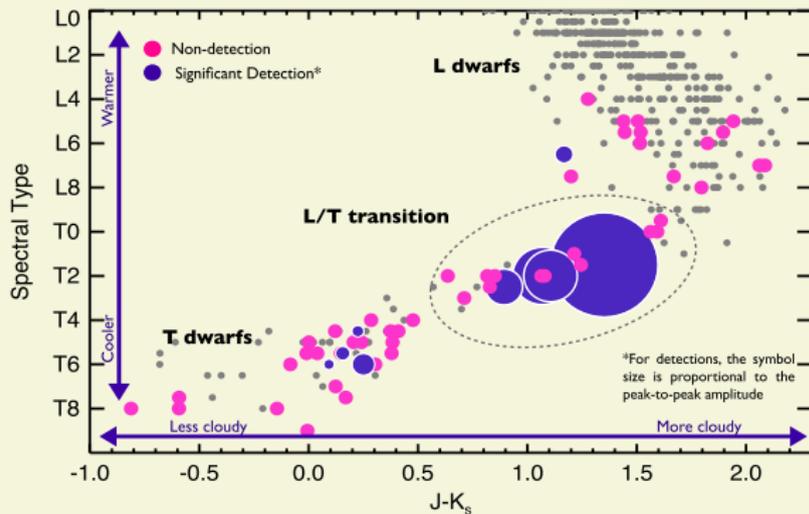

- L-dwarfs (~ 2200 - 1600 K) and T-dwarfs (~ 1600 - 500 K) have undergone radiative cooling with age (~ 1 Gyr), shrinking to the size of Jupiter.
- Lack of efficient braking mechanisms cause them to conserve momentum by spinning increasingly faster, so that some BDs approach the Roche break-up limit

Need for brown dwarf (BD) modeling: oblateness

- Many brown dwarfs have a period of rotation between 2-5 hrs, covering the full range of oblateness between $\eta = 0 - 0.33$

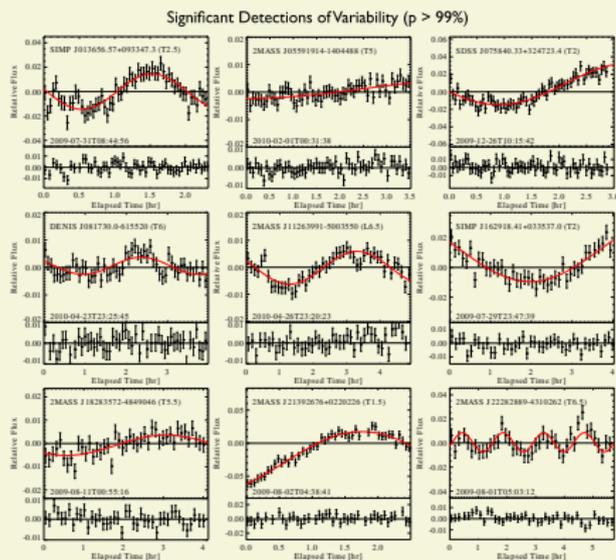

Need for brown dwarf (BD) modeling: patchy clouds

(Radigan et al. 2014)

- Late L- and early T-dwarfs start seeing the fragmentation and precipitation of clouds near the photosphere, revealing deeper layers of the atmosphere

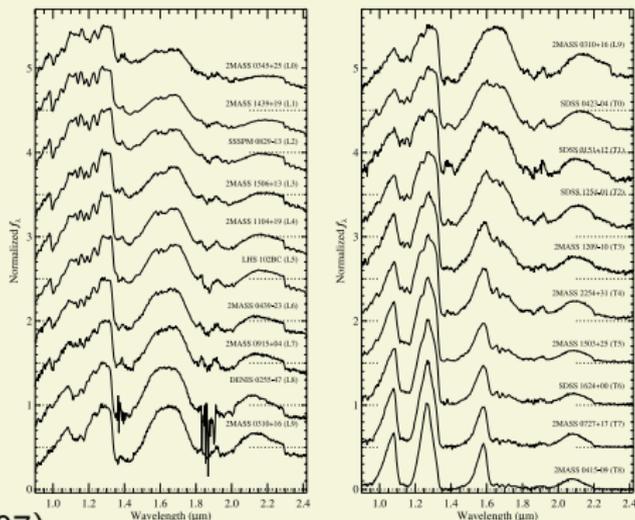

Need for brown dwarf (BD) modeling: patchy clouds

(Radigan et al. 2014)

- High quality observations of photometric variability confirm patchy clouds to be a dominant feature of BDs in L/T-transition

Need for brown dwarf (BD) modeling: patchy clouds

(Burgasser et al. 2007)

- L-dwarfs are only affected by weak absorption due to H_2O in the NIR, while the deeper atmospheric column of T-dwarfs feature strong pressure-broadened alkali lines in the optical, near-saturation CH_4 absorption in the NIR, and H_2 CIA near the K-band.

3 Modeling studies

Need of a framework to model oblate BDs with patchy clouds

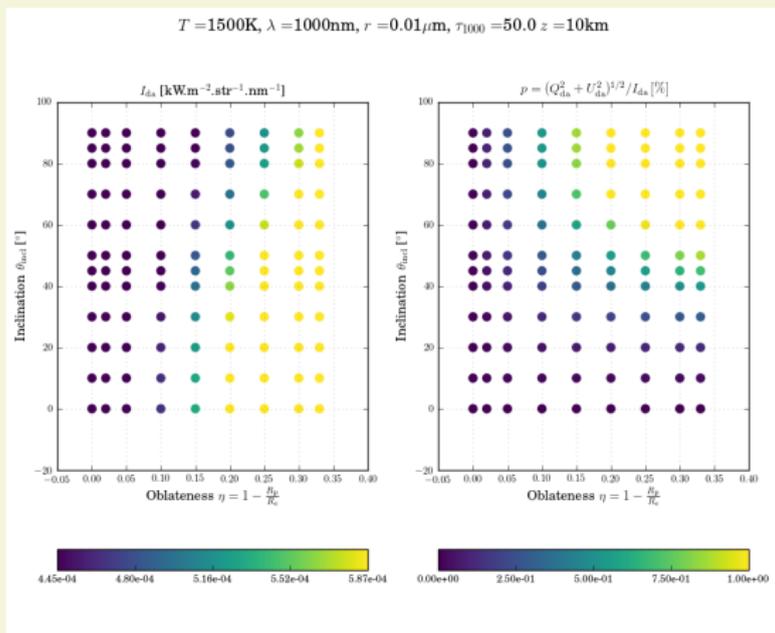

- Semi-analytical 3D framework based on the 1D polarized RTM vSmartMOM (Sanghavi et al. 2014)
- Fast and accurate modeling of scattering by distributions of spherical cloud grains (Sanghavi 2013, Sanghavi et al. 2015)
- Allows for the first time simultaneous, polarized simulations of oblateness and any number of cloud patches at a given inclination angle

Preliminary assumptions

- For generality, we assume a gray atmosphere, so that the BD emits as a black body of temperature T_{eff} .
- To deal with the spectral variations in photospheric depth due to atmospheric opacities, we currently assume two extreme cases:
 - ① A completely non-absorbing atmosphere, for which the photosphere is at the bottom of the atmospheric (gaseous) column (BOA)
 - ② An almost completely opaque atmosphere, for which the photosphere is almost at the TOA
- The modeled cloud consists of a log-normal distribution of spherical, Mie-scattering, silicate grains and always occurs above the photosphere

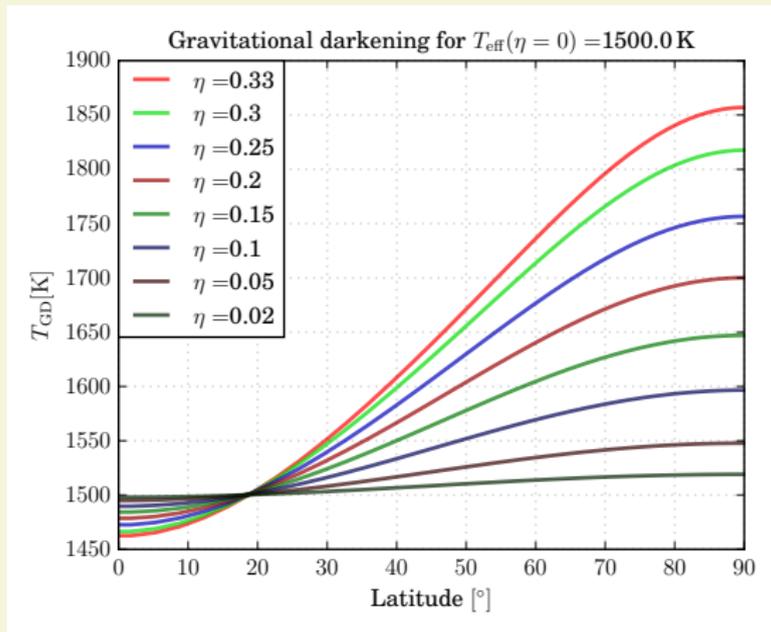

vSmartMOM: first simulations of patchy clouds on oblate BDs (Sanghavi et al., under review, ApJ)

Effect of oblateness and inclination angle

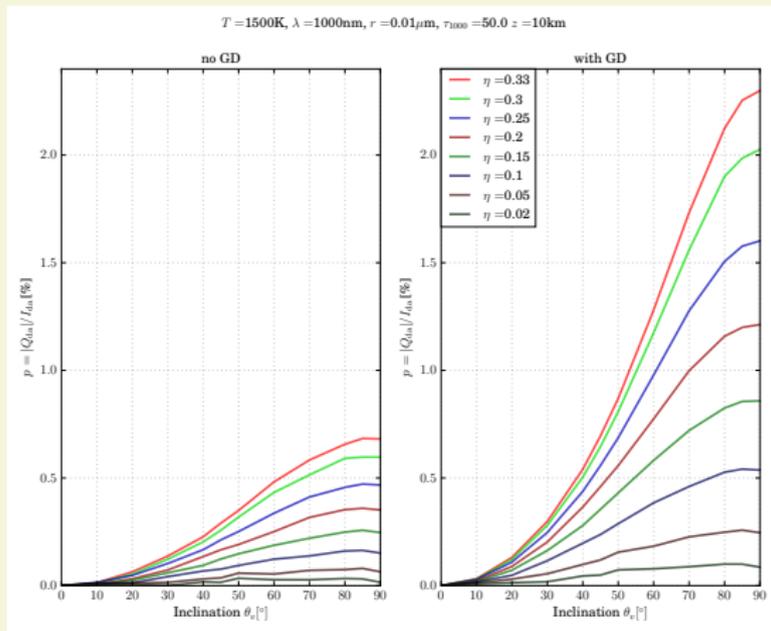

- Both intensity and polarization are functions of oblateness, η , and inclination angle, θ_{incl}

Gravitational darkening

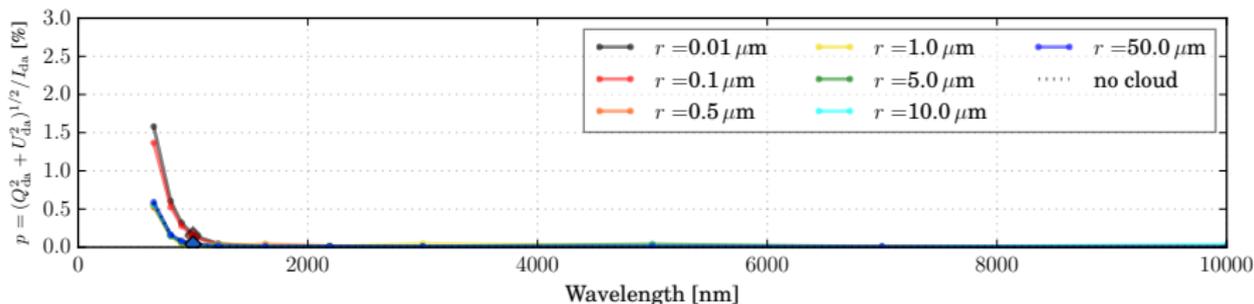

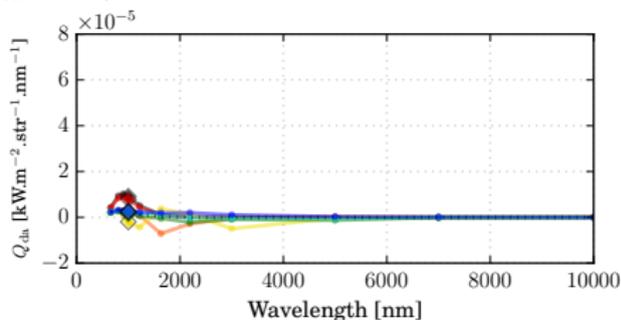

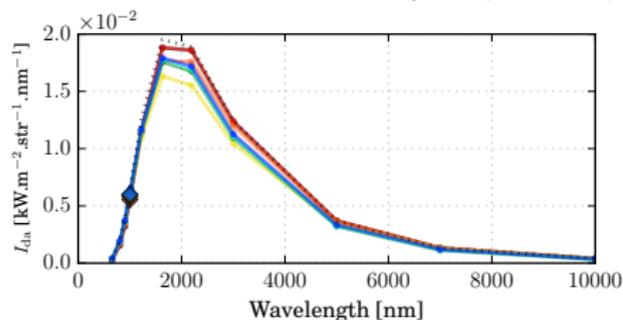

Gravitational darkening

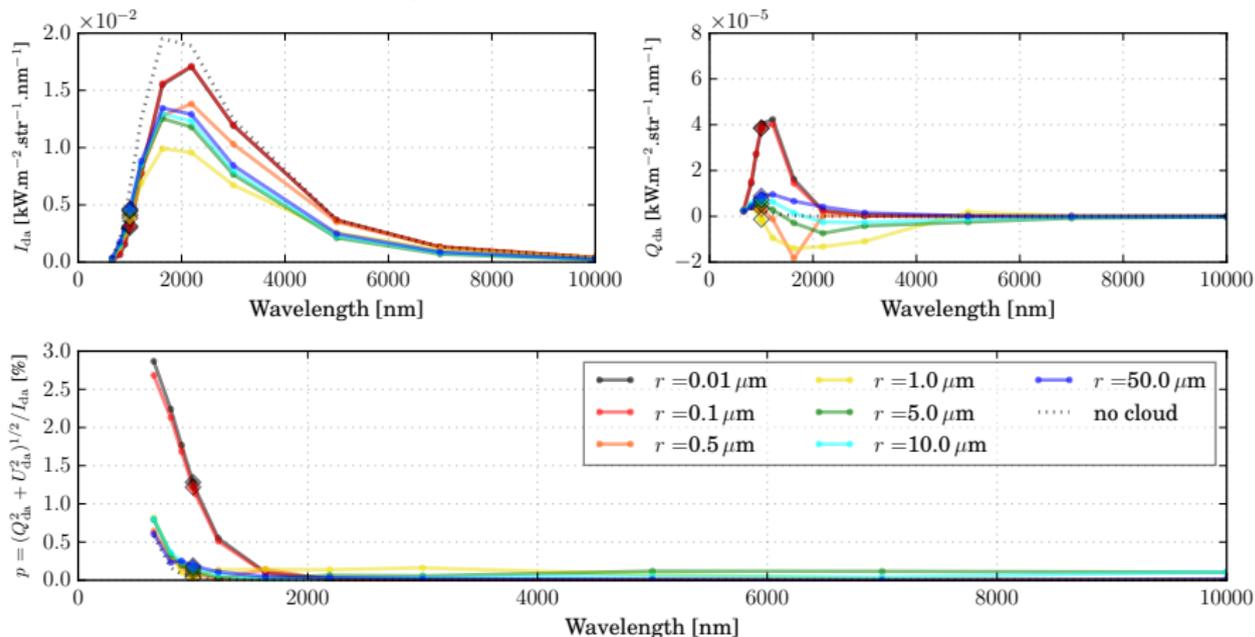

Effects of cloud properties: optical thickness, cloud grain size

$\eta = 0.3, \theta = 90.0^\circ, \tau_{\text{scat}} = 0.1$, with GD

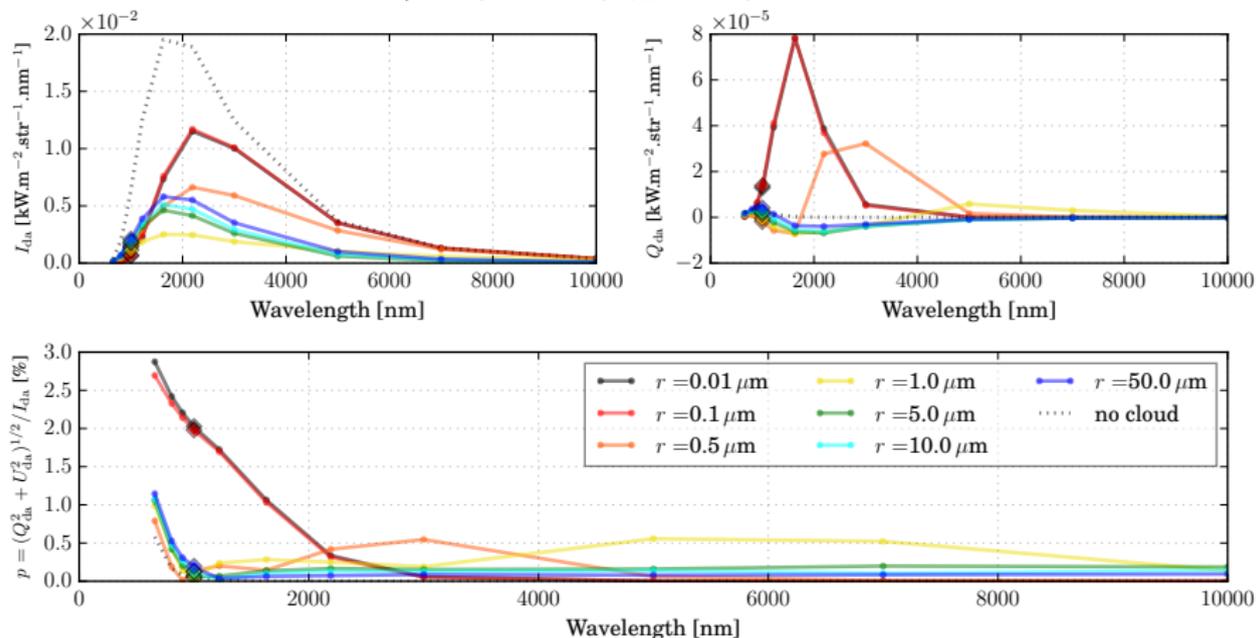

Effects of cloud properties: optical thickness, cloud grain size

$\eta = 0.3, \theta = 90.0^\circ, \tau_{\text{scat}} = 1.0$, with GD

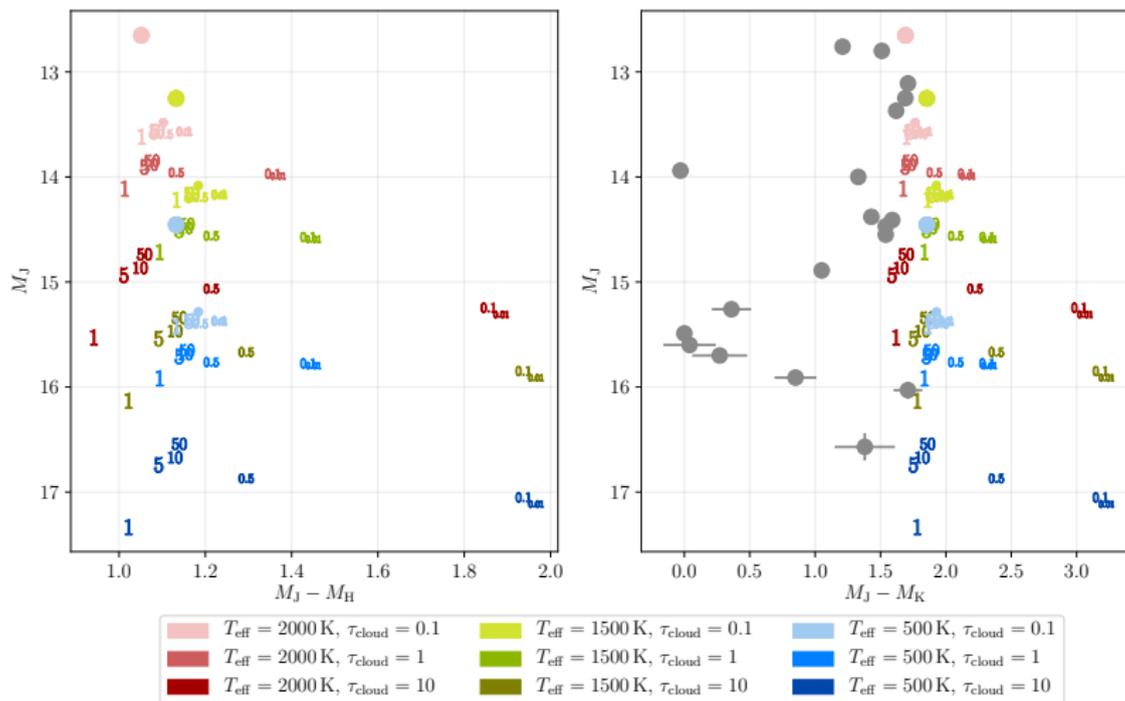

Effects of cloud properties: optical thickness, cloud grain size

$\eta = 0.3, \theta = 90.0^\circ, \tau_{\text{scat}} = 10.0$, with GD

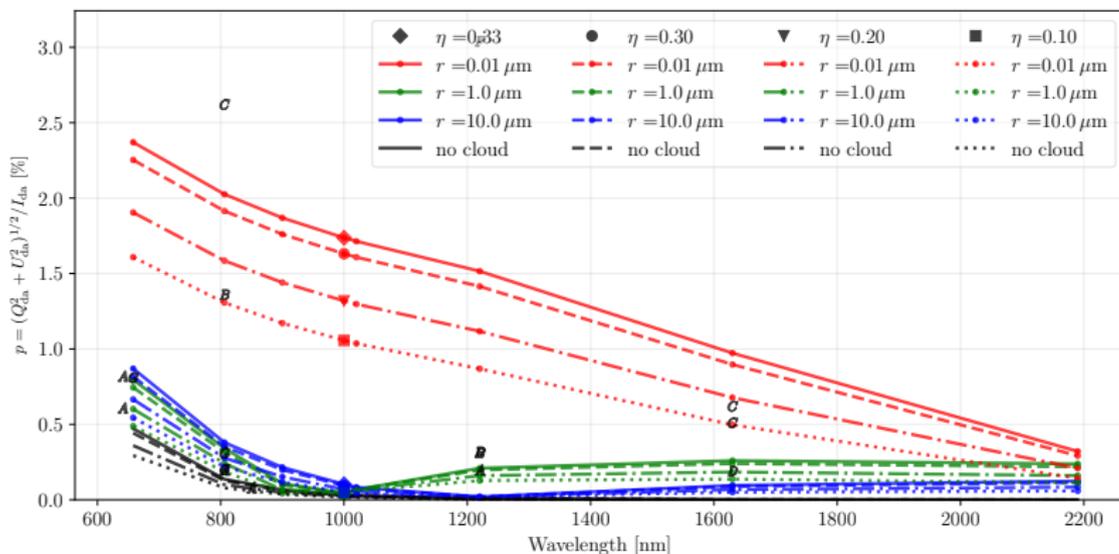

Photometry: Need for detailed consideration of opacity

Polarimetry: Effect of clouds

Photosphere at BOA, $T_{\text{eff}} = 2000 \text{ K}$

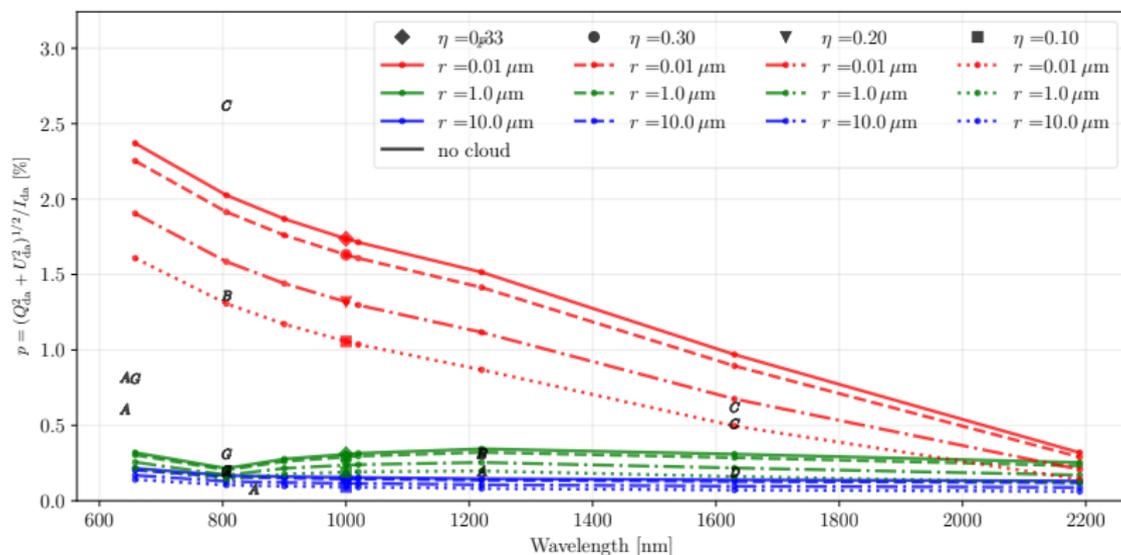

$T_{\text{eff}} = 2000.0 \text{ K}$, $\theta = 90.0^\circ$, $\tau_{\text{scat}} = 10.0$, with GD, $p_{\text{cutoff}} = p_0$

Polarimetry: Effect of clouds

Photosphere at TOA, $T_{\text{eff}} = 2000 \text{ K}$

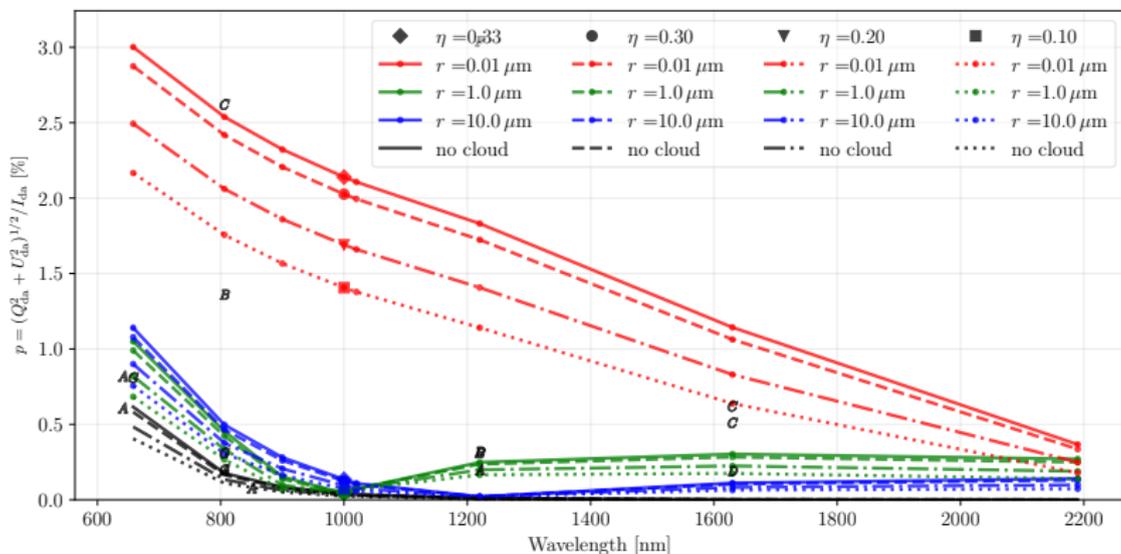

$T_{\text{eff}} = 2000.0 \text{ K}$, $\theta = 90.0^\circ$, $\tau_{\text{scat}} = 10.0$, with GD, $p_{\text{cutoff}} \sim 0$

Polarimetry: Effect of clouds

Photosphere at BOA, $T_{\text{eff}} = 1500 \text{ K}$

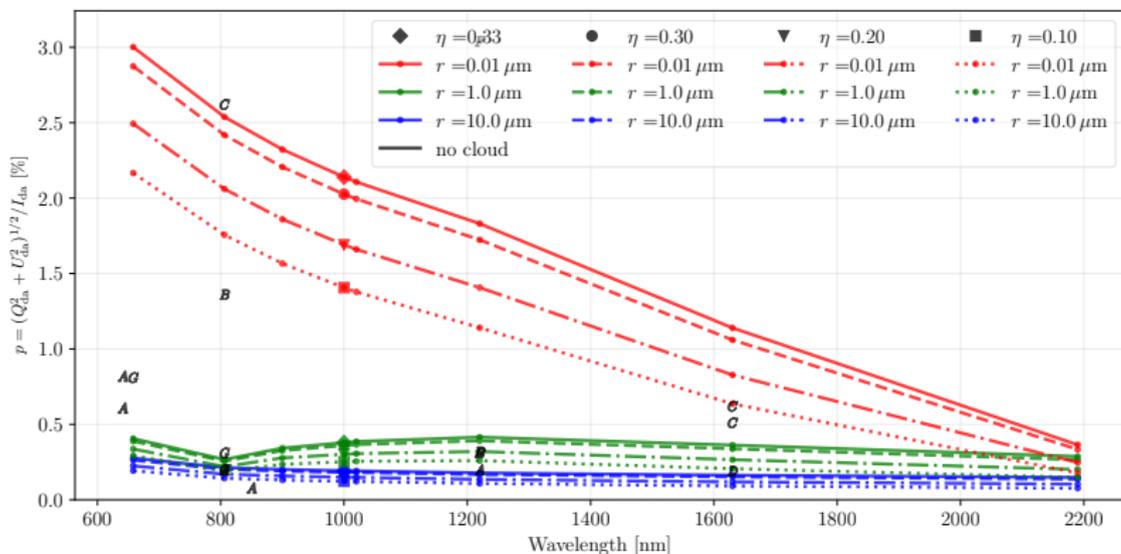

$T_{\text{eff}} = 1500.0 \text{ K}$, $\theta = 90.0^\circ$, $\tau_{\text{scat}} = 10.0$, with GD, $p_{\text{cutoff}} = p_0$

Polarimetry: Effect of clouds

Photosphere at TOA, $T_{\text{eff}} = 1500 \text{ K}$

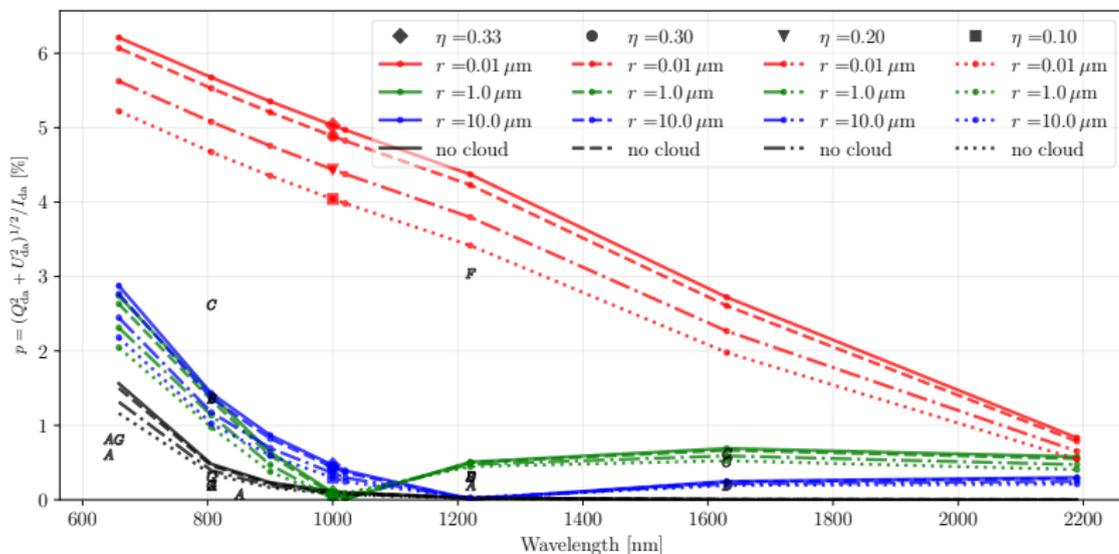

$T_{\text{eff}} = 1500.0 \text{ K}$, $\theta = 90.0^\circ$, $\tau_{\text{scat}} = 10.0$, with GD, $p_{\text{cutoff}} \sim 0$

Polarimetry: Effect of clouds

Photosphere at BOA, $T_{\text{eff}} = 500\text{ K}$

$T_{\text{eff}} = 500.0\text{ K}$, $\theta = 90.0^\circ$, $\tau_{\text{scat}} = 10.0$, with GD, $p_{\text{cutoff}} = p_0$

Polarimetry: Effect of clouds

Photosphere at TOA, $T_{\text{eff}} = 500\text{ K}$

$T_{\text{eff}} = 500.0\text{ K}$, $\theta = 90.0^\circ$, $\tau_{\text{scat}} = 10.0$, with GD, $p_{\text{cutoff}} \sim 0$

Summary

- Gravitational darkening can significantly amplify the polarization due to oblate BDs, allowing for the first time polarimetric measurements of over 2% to be simulated
- DoP increases with increasing oblateness and inclination angle (edge-on viewing is most polarizing)
- Optically thick clouds cause more dimming, larger cloud grains cause blueing of the SED
- Polarization due to small grains is most effective at optical-NIR wavelengths, because of which this spectral region is most sensitive to the location of the photosphere in the atmospheric column
- Effects of atmospheric opacity need to be accounted for, especially for simulations of T-dwarfs - this is currently underway using Renyu Hu's thermochemistry model EPACRIS
