III. Solar Sail Flight System Technology

Session Facilitator:
Gregory P. Garbe
Outline

• Executive Summary
• Solar Sail Capabilities to be Validated by ST9
• Solar Sail TCA/Mission-Level Validation Objectives for ST-9
Executive Summary

- Workshop Addresses Following Technology Areas
  - Sail system design metrics & scaling
  - Controlled sail deployment in an orbital/space environment
  - In-space characteristics of the deployed sail and structure
  - Sail system design metrics & scaling
  - Controlled sail deployment in an orbital/space environment
  - In-space characteristics of the deployed sail and structure
  - Sailcraft attitude control
  - System propulsion performance
  - Design approach and processes

- Sessions Topics
  - Future space science mission needs
  - Desired workshop products
  - Technology splinter session discussions
  - Needs/potential capabilities assessments

- Splinter Session Topics
  - Modeling and Simulation of Deployed Solar Sails
  - Solar Sail Material Qualities and Environmental Characteristics
  - Pointing, Control, and Navigation Technology for Solar Sails
  - Solar-Sail Packaging Deployment, and Structure Technologies
Key Observations and Recommendations

- Need the corroboration between quantitative models and ground testing for all major subsystem
- Scale of validation flight needs to be no smaller than 1/3 of future science mission
- Two most important Solar Sail Figure of Merits are:
  1. Root Sail Area (\(L_{RSA}\)):
     - Square root of sail's reflective area
  2. Sail system areal density (\(\sigma_S\)):
     - Mass sail system (e.g., membrane, trusses, GNC, Diagnostics, etc.) divided by reflective area

Recommendations for ST-9 Flight Experiment

- Need comprehensive diagnostic package that quantitatively measures the system performance and interaction with its environment
- \(L_{RSA}\) should be minimum of 50 m
## Solar Sail Capabilities to be Validated by ST9 (1 of 2)

Solar Sail Figures of Merit required capabilities for Science Missions

Notes:  1) ISP Ground Demo $\sigma_T$ assumes non-sail system mass of 10 kg

2) Solar Sail Propulsion is being studied to determine its viability to SSE Missions
Solar Sail TCA/Mission-Level Validation Objectives for ST-9

Sail Validation Objectives

1. Validate sail system design metrics & scaling
2. Validate controlled sail deployment in an orbital/space environment
3. Validate in-space characteristics of the deployed sail and structure
4. Validate sailcraft attitude control
5. Validate system propulsion performance
6. Validate design approach and processes
**Objective 1. Validate Sail System**

IV. Formation Flying Technology

Session Facilitator:
Jesse A. Leitner
Outline

- Executive Summary
- Formation Flying Capabilities to be Validated by ST-9
- Overview and Introduction
  - What is Formation Flying?
  - Scope of the ST-9 Formation Flying Technology Capabilities Area
- Science Mission Capabilities Roadmap and Timeline
- Technology Capabilities Roadmap
- Figure Of Merit (FOM) Definitions
- State Of The Art
- Acronym List
Executive Summary

• Workshop Addresses Following Technology Areas
  – "Precision Formation Flying" (PFF): The frequency and tightness of formation control (not just navigation)
  – Continuous process of maintaining or tracking a desired geometric configuration

• Sessions Topics
  – Future space science mission needs
  – Desired workshop products
  – Technology splinter session discussions
  – Needs/potential capabilities assessments

• Splinter Session Topics
  – Relative Navigation, Relative Attitude, and metrology sensors and algorithms: the engineering measurements of formation flying
  – Formation Control algorithms and actuators: the logic and actuation hardware to calculate and produce forces needed for formation flying
  – Intersatellite Communications, timing, time transfer: systems to share data between the spacecraft, synchronize spacecraft, and disseminate commands
  – Modeling, Simulation, and Mission Design Tools: tools and methodologies needed to verify performance on the ground
  – Autonomous Constellation Management and Control: the high level control layer for multi-spacecraft operations
Executive Summary (continued)

• Key Observations and Recommendations
  – The big challenge will be to craft a mission concept which is affordable and technology-centered, and has enough elements with sufficiently high performance to truly alleviate the future risks of upcoming strategic Space Science missions.
  – This team must find the right mix of proving relevance, reducing risk, and controlling cost.
  – For example, a scientific or instrument-centered demonstration - i.e., an interferometry or imaging demonstration, while providing the ultimate validation if successful, may have the tendency to break the bank.

• Recommendations for ST-9 Flight Experiment
  – Importance of exercising system elements in an integrated manner
  – Demonstrate mature component technologies in an integrated package
  – Allocate virtually all risk into the system-level aspects instead of component-level

*Formation Flying Technology*
Overview and Introduction

- Precision Formation Flying System Technology is critical for a broad range of future NASA Space Science missions
  - TPF (ASO)
  - MAXIM, MAXIM PF (SEU)
  - Stellar Imager (SEC)
  - LF, PI, SPECS, ...
- The “precision” qualifier carves out a somewhat well-defined niche in the formation flying field with the following characteristics
  - Continuous and robust, possibly high bandwidth intersatellite communications
  - On-board relative navigation/bearing at high data rate with high-precision through the communication links
  - Continuous formation control at high bandwidth and high-precision through the communication links
  - Highly-optimized formation/mission design and analysis
  - Integrated hardware-in-the-loop, high-fidelity simulations
  - Autonomous and robust closed-loop on-board control during science gathering
What is Formation Flying?

**Engineering definition:** the tracking or maintenance of a desired separation between/among two or more spacecraft

**Science definition:** the collective use of multiple spacecraft to perform the function of a single, large, virtual instrument

ST-9 you are here

Rendezvous Docking
In the context of ST-9, we will focus on the problem of "Precision formation flying"

- Precision, in this case, refers to a continuous process of maintaining or tracking a desired geometric configuration
- Collectively, it is the frequency and tightness of formation control (not just navigation)

Since the focus is on demonstrating technologies critical to future NASA Space Science Enterprise missions, the orbits of primary interest: are HEO, libration points, heliocentric, deep space
Science Mission Capabilities
Roadmap and Timeline

Capability

- Loose formations

**Formation Flying Technology**
Figure Of Merit (FOM) Definitions

- Relative position estimate: the estimated value of relative position between spacecraft
- S/C Formation Control: the controlled separation between selected references points between two spacecraft.
- Intersatellite communications bandwidth: the number of bits of data passed from one spacecraft to another.
- Formation geometric dimension: the number of dimensions in free-space spanned by the desired formation
State Of The Art

- Relative position estimate: 1 micron range change, 2 cm ranging (post-processed)
- Formation control: kms (EO-1/LS-7)
- Intersatellite comm data rate: 300 Mbps (large EIRP) TDRSS
- Formation geometric dimension: 1 (rendezvous docking)
- Number of s/c managed collectively: ~50 (from the ground)

V. System Technology for Large Space Telescopes

Session Chair:
Juan A. Roman
Outline

- Executive Summary
- Large Telescope Capabilities to be Validated by ST9
- Overview and Introduction
- Ultimate Capabilities
- Science Mission Capabilities Time Line
- Goal of Splinter Sessions
Executive Summary

- **Workshop Addresses Following Technology Areas**
  - Issues of large (10-25m), cryogenic (4K), low mass telescope systems.

- **Sessions Topics**
  - Future space science mission needs
  - Desired workshop products
  - Technology splinter session discussions
  - Needs/potential capabilities assessments

- **Splinter Session Topics**
  - Large Telescope System Simulation and Modeling
  - Materials, Structures, Actuators, and Controls for Fabrication, Packaging and Deployment of Large Telescope Systems
  - Optical Correction and Active Figure Control for Large Aperture Telescopes
  - Thermal Control at Cryogenic Temperatures for Large Aperture Telescopes
  - Structure and Control Dynamics of Large Telescope Systems
Executive Summary (continued)

- **Key Observations and Recommendations**
  - ST-9 can accelerate development of needed technology before they are mature enough to be applied in a strategic scientific mission.

- **Recommendations for ST-9 Flight Experiment**
  - Applicable to a Far-Infrared (20 - 600μm) mission with 10 – 25m telescope at 4 K
  - ST-9 can validate several of the following critical technologies
    - Deployable low areal density aperture scalable to diameter >10m
    - Passive cooling (with sunshields / radiators) to ~20 K
    - Active cooling of large structures from ~20 K to ~4 K
    - Integrated system modeling of end-to-end performance
    - Pointing stability consistent with telescope design
    - Wavefront sensing and control
  - Orbit traceable to target mission (e.g., L2), however:
    - Will tolerate thermal and dynamical differences necessitated by other orbits (e.g., LEO, GTO)
    - Will tolerate contamination and radiation differences

* These required capabilities are a critical subset; other important capabilities may not be listed here.

---

*Large Space Telescopes* V - 5
Large Space Telescopes

Motivation for a Large Cryogenic Space Telescope

- A key element of the SSE mission series is a large space telescope, 10-meter diameter, cryogenically cooled to 4 K and optimized for wavelengths between 40 μm and 1 mm.
- The combination of aperture diameter and telescope temperature will provide a raw sensitivity improvement of more than a factor of 1000 over presently-planned missions, therefore, capable of conducting groundbreaking research.
- In consideration of its enormous scientific potential, such a mission was recommended by the National Academy of Sciences Astronomy Decadal Committee as "the next step in exploring this important part of the spectrum."

State of the Art

- The JWST is considered to be the departing point for future missions.

Enabling Capabilities

- Very lightweight mirrors
- High dynamic wavefront sensing and control
- Active and passive cooling below 10 K
- Validation of end-to-end models in relevant environment
Overview and Introduction

ST-9

• Critical stepping stone toward making possible future Large Space Telescopes.
• Will enable the next breakthrough in technology capabilities that requires in-space system validation.
• Development of needed technology capabilities can easily take a decade or more before they are mature enough to be applied in a strategic scientific mission.
  – ST-9 can accelerate this process
• The focus is on system "validation" to address the gaining of understandings that are useable beyond the confines of the specific hardware, e.g., scaling based on correlations with analytical models.
“Ultimate Capabilities”

- Some of these capabilities are:
  - Building of deployable large, low areal density mirrors and their associated structural components for operation at ambient and cryogenic temperatures.
  - Wavefront control with active control of optical elements and microdynamic and thermal structural effects to surpass diffraction-limited performance.
  - Providing active and passive cooling for full-aperture, all-optics cooling to ~4K and other technologies for achieving a similar reduction in thermal system noise for infrared space telescope systems.
  - Robust end-to-end modeling of telescope system and validation of system model.
Science Mission Capabilities
Time Line

~2010

~2020
Time

~2030

Large Space Telescopes
Areal Density Figure of Merit

Areal Density = Mass per unit area (Kg/ m²).
It includes mirror, actuators, cables and backing structure of optical system.

<1Kg/ m², <$500K/m² <4 K, 10 – 25 m dia.
with high packing density (fit in EELV)

ST-9:
~5Kg/ m², <$1M/m²,
<10K, diffraction limited
at 20 - 40um

AMSD: 15Kg/ m²,
$5M/m², 30-50K,
50nmRMS
Goal of Splinter Sessions

- Identify and refine the capabilities needed for future Large Space Telescopes missions under consideration by the Space Science Enterprise.
- Define validation requirements for each of the technology capabilities in a quantitative manner and at a realizable level of technology maturity to support a 2008 launch date.
- Opportunity to obtain inputs from the broadest possible base – industry, academia, government.
Acronyms

- ST – Space Technology
- EELV – Evolved Expendable Launch Vehicle
- L2 – Libration Point 2
- LEO – Low Earth Orbit
- GTO – Geostationary Transfer Orbit
- JWST – James Webb Space Telescope
- TPF – Terrestrial Planet Finder
- SAFIR – Single Aperture Far IR telescope “sapphire”
- SSE - Space Science Enterprise
- SUVO – Space Ultraviolet Observatory
- AMSD – Advanced Mirror System Demonstrator
VI. Descent and Terminal Guidance for Pinpoint Landing and Hazard Avoidance

Session Chair:
Dr. Sam W. Thurman
Executive Summary

- **Workshop Addressed Following Technology Areas**
  - “Pinpoint” Landing
  - Hazard Detection and Avoidance

- **Sessions Topics and Activities**
  - Future space science mission needs
  - Desired workshop products
  - Technology splinter session discussions
  - Needs/potential capabilities assessments

- **Splinter Session Topics**
  - Guidance, Navigation and Control (GN&C) Systems
    - Modeling and Simulation
    - Sensors/Algorithms for Guidance and Navigation
    - Aerodynamic/Propulsive Maneuvering System Options
  - Terrain Sensing and Hazard Recognition Systems
    - Terrain Sensors and Hazard Detection/Recognition Algorithms
    - Architectural Options for GN&C Systems with Terrain Sensors

- **Key Splinter Session Observations and Recommendations**
  - Target body environment characteristics driving descent/landing system design tend to group into airless bodies and those with atmospheres
  - Mars environment viewed as stressing case in many important aspects
    - Presence of atmosphere allows/requires use of aerodynamic deceleration systems
    - Low atmospheric density effectively also requires propulsive maneuvering systems to accomplish targeted landing with hazard avoidance capability
• **Recommendations for ST-9 Flight Experiment**
  
  - **Important to exercise system elements in an integrated manner**
    - Onboard navigation incorporating both inertial and terrain sensing capability
    - Hazard recognition, safe target landing site selection, and aerodynamic/propulsive steering using navigation data
  
  - **Terrestrial sub-orbital (via sounding rocket boost) or descent-from-orbit flight test mission recommended**
    - Lander Test Vehicle with Following Capabilities
      - Onboard Navigation
        » Inertial sensors and prototype terrain sensor(s)
        » Navigation algorithms and computations for inertial/terrain sensor data fusion
        » Hazard recognition and safe landing site selection algorithms and computations
      - Onboard Guidance & Control
        » Targeted parachute descent using "smart" parachute deployment logic
        » Consider propulsive terminal descent to soft landing (if it fits cost target)
  
  - **Rationale**
    - Enables operation of integrated GN&C system in flight-like manner
    - Dynamical scaling can be used to create flight dynamics environment representative of many different "smart" landing mission environments
    - Near-Earth environment offers low-cost multiple test flight opportunities and ability to acquire many detailed measurements for model correlation and validation
  
  - **This approach would validate a GN&C system architecture capable of scaling to meet most projected future mission needs over next 10-15 years**

Descent/Terminal Guidance for “Smart” Landing
Overview and Introduction

- **Future Space Science Mission Needs**
  - Variety of desired missions for planetary surface exploration
    - Lunar and Mars exploration and sample return
    - Comet and asteroid sample return
    - Europa lander
    - Venus and Titan exploration
  - Many scientific objectives benefit/enabled by new engineering capabilities for delivery of scientific payloads to planetary surfaces
    - "Pinpoint" Landing
    - Hazard Detection and Avoidance

- **Workshop Conducted with Following Objectives**
  - Identify potential mission needs and requirements via diverse group of engineering experts from government, industry, academia
  - Survey component/subsystem technologies for meeting these needs
    - Functionality and performance
    - Technology maturity, test/validation requirements and approaches
    - Modeling and scaling of test/validation results to different mission environments
  - Synthesize survey results to map and prioritize technology candidates versus mission needs
  - Formulate recommendations for ST-9 Flight Experiment scope and content to be considered during subsequent Pre-Phase A and Phase A study effort

*Descent/Terminal Guidance for "Smart" Landing*
“Smart” Landing Overview

- “Smart” Landing Technologies
  - Pinpoint Landing
  - Hazard Detection & Avoidance

- Science Mission Benefits
  - Ability to reach landing sites which may lie in areas containing hazardous terrain features
    - Escarpments
    - Craters
    - Slopes and rocks
  - Ability to land accurately at select landing sites of high science value
    - Small terrain types/features or isolated locations (e.g., safe target site within larger region of hazardous terrain)

- State of the Art
  - No existing system-level capability
  - Some previous examples of propulsive maneuvering in Apollo/Viking era
    - Apollo Lunar Module descent/landing
    - Surveyor and Viking Landers
  - Some recent terrestrial examples of terrain sensing in “smart” weapons

- Technical Approach
  - Onboard Navigation
    - Accurately determine current and predicted lander flight path
  - Terrain Sensing
    - Sense terrain characteristics and recognize hazardous features
    - Identify safe landing site that can be reached given lander’s maneuverability
  - Onboard Guidance
    - Provide maneuvering capability (aerodynamic or propulsive) to steer lander to touchdown at desired safe landing site
## Science Capabilities Roadmap

</tr>
</tbody>
</table>
Technology Capabilities Roadmap

- **Current Generation (today)**
  - **Landing Accuracy**
    - Bodies with Atmosphere: 100-300 km
    - Airless Bodies: 1-10 km
  - **Hazard Detection and Avoidance**
    - none

- **Next Generation (incorporating results from ST-9)**
  - **Landing Accuracy**
    - Bodies with Atmosphere: 3-6 km
    - Airless Bodies: 0.1-1 km
  - **Hazard Detection and Avoidance**
    - detecting 99% of rocks > 0.75 m; detect > 20° slopes
    - 100-200 m divert capability

- **Future Generation Goals (beyond ST9)**
  - **Landing Accuracy**
    - Bodies with Atmosphere: < 100 m
    - Airless Bodies: < 10 m
  - **Hazard Detection and Avoidance**
    - detecting 99% of rocks > 0.2 m; detect / analyze terrain features at and near landing site (including non-geometric hazards)
    - 0.5-5.0 km divert capability

*Descent/Terminal Guidance for “Smart” Landing*
Figure Of Merit (FOM) Definitions

- **Pinpoint Landing**
  - **Delivery Accuracy**
    - Miss distance between target landing site and actual landing location

- **Hazard Detection and Avoidance**
  - **Hazard detection/recognition**
    - Detection and recognition of geometric and non-geometric terrain hazards
      - Detection and recognition of geometric hazards such as craters, escarpments, rocks, slopes, etc.
        » Key metrics: probability of missed detection of hazardous terrain and probability of false positive from non-hazardous terrain
      - Detection and recognition of non-geometric hazards such as terrain areas with low/insufficient bearing strength
        » Key metric is similar to above
  - **Maneuver capability for hazard avoidance**
    - Site redesignation capability versus altitude/velocity regime during descent
VII. Aerocapture System Technology for Planetary Missions

Session Facilitator:
Michelle Munk

Presentation to NMP ST9 Workshop
Washington, D.C.
February 2003
Outline

• Executive Summary
• Aerocapture Capabilities to be Validated by ST9
• Aerocapture Overview
  – Aerocapture as an Enabling Technology
• Technology Areas to be Addressed by ST9
  – Experiment Requirements
• Science Capabilities Roadmap
  – Aerocapture Mission Summary
• Technology Roadmap
• State of the Art
• Figures of Merit Definitions
Executive Summary

- The Splinter Sessions Focused on the Following Technology Areas
  - System and Performance Modeling
  - Aerodynamics and Aerothermodynamics
  - Thermal Protection Systems/Structure
  - Guidance, Navigation, and Control (GN&C)

- Session Topics
  - Future space science mission needs
  - Desired workshop products
  - Technology splinter session discussions
  - Needs/potential capabilities assessments
Executive Summary (continued)

Key Observations

- Aerocapture is applicable to all planetary destinations with suitable atmospheres (Venus, Earth, Mars, Jupiter, Saturn, Titan, Uranus, and Neptune)

- The primary advantage of aerocapture is propellant mass savings. The net vehicle mass savings range from 20-80% depending on the destination and can manifest themselves in terms of smaller, cheaper launch vehicles or increased payloads.
  - Preliminary results indicate that some missions (e.g. Neptune Orbiter) cannot be done without aerocapture because they won't fit on the largest available launch vehicle (Delta IV heavy).
  - Aerocapture can also reduce trip time (by allowing higher arrival speeds than chemical capture can feasibly accommodate), and enable new missions with increased flexibility

- Aerocapture is a systems technology in which most of the elements already exist due to development in other aeroentry applications. The critical next step is to assemble these elements into a prototype vehicle, fly it in the space environment and thereby validate the design, simulation and systems engineering tools and processes
  - This need is very well matched to the NMP program objective that ST-9 be a systems level validation experiment

- ST-9 flight experiment is key to making aerocapture technology available to science missions
Executive Summary (continued)

- **Recommendations for ST-9 Flight Experiment**
  - ST-9 should validate the most mature and immediately useful vehicle configuration, which is the blunt body aeroshell
    - Blunt body aeroshell systems provide robust performance for aerocapture at all "small body" destinations in the solar system (Mars, Titan, Venus, Earth)
    - The validation will be directly relevant to other aeroshell geometries (as will be needed for the gas giants) for the guidance, simulation and systems engineering disciplines
  - The ST-9 flight validation must demonstrate a drag delta-V of 2 km/s, in order to involve all of the essential physics of the problem and serve as an acceptable validation of aerocapture
    - Although the ST-9 cost cap precludes a "true" aerocapture flight test involving a hyperbolic to elliptic orbit change effected by atmospheric drag, this objective can be accomplished with an elliptical-to-elliptical orbit change.
  - The ST-9 flight test should include an autonomous periapse raise maneuver after the atmospheric portion of the flight
  - The ST-9 vehicle should incorporate diagnostic instrumentation to the maximum extent possible under the cost cap
    - The two priorities are to get information about the hypersonic flow field around the vehicle and to quantify the performance of the thermal protection material.
  - The ST-9 vehicle should baseline mature TPS and structural materials to minimize risk
    - However, it is recommended (if affordable given the cost cap) that the vehicle incorporate a test coupon of one or more new TPS materials that are candidates for future aerocapture and/or aeroentry missions at other planets. These coupons should be incorporated in such a way that their failure does not compromise the overall flight test experiment

</table>
What is it?
- Aerocapture is an orbit insertion flight maneuver executed upon arrival at a planet.
- Spacecraft flies through the atmosphere and uses drag to effect multi-km/s deceleration in one pass.
- Requires minimal propellant for attitude control and a post-aerocapture periapse raise maneuver.

Benefits
- Significant reduction in propellant load; arrival mass can be reduced by 20-80% for the same payload mass depending on the mission.
- Achieves the required orbit faster than with aerobraking or SEP alternatives (hours vs weeks/months).
- Can result in reduced flight times since arrival speeds can be higher than for propulsive capture.

State of the Art
- Never been attempted before.
- Considerable relevant experience from past aeroentry and aerobraking missions.
- Sufficient technical maturity exists for a flight test experiment.

Primary Technical Approach
- Spacecraft carried inside a protective aeroshell.
- Aeroshell provides both thermal protection and aerodynamic surface functionality.
- Aeroshell cutouts and feedthroughs enable full spacecraft functionality during cruise.
- Automatic guided flight through atmosphere using specialized algorithms/software.
- Aeroshell jettisoned after capture.
Aerocapture is an Enabling Technology

- Aerocapture can save so much propellant mass that it enables missions that cannot otherwise be done
  - Propulsive orbit insertion obeys the rocket equation: $M_{\text{fuel}} \sim \exp(\Delta V)$
  - Aerocapture mass is predicted to scale almost linearly: $M_{\text{AC}} \sim \Delta V$

Aerocapture Technology Areas to be Addressed by ST-9

- Complete systems level test of a free-flying vehicle in order to validate the design, simulation, and systems engineering tools and processes.
- This validation will directly address flight mechanics, vehicle design, systems engineering and integration, no matter what the future planetary destination is.
- This validation will partially address aerothermodynamics and TPS, since the applicability to future missions is more limited because of the specialized needs of the different destinations.
Experiment Requirements

- In a single atmospheric pass, utilize bank angle modulation through an atmosphere to remove the necessary amount of delta V from the vehicle approach trajectory to achieve the target orbit.
  - The delta V achieved during this maneuver must be on the order of 2 km/s to validate all phases of the guidance and achieve hypersonic continuum aerodynamics
- Validate a mature and immediately useful vehicle configuration
- Perform an autonomous periapse raise maneuver after the atmospheric portion of the flight
- Utilize diagnostic instrumentation to the maximum extent possible, to acquire information about the hypersonic flow field and quantify the performance of the thermal protection material.
  - The information obtained will be the key to model validation and technology infusion
ST-9 Feed-Forward to Science Capabilities

- 1m-2m Carbon-Carbon structural/TPS system
- 1m-2m ablative structural/TPS system
- TPS integrated heat flux sensors
- TPS integrated recession sensors
- Towed ballute prototype
- Aerocapture at Titan: Systems definition study complete
- Aerocapture at Neptune: Systems definition study complete
- Attached ballute(s) prototype design
- Aerocapture at Mars: trade studies complete
- Aerocapture at other SSE destinations: trade studies complete
- Aerocapture flight demo proposal to New Millennium complete
- Aerocapture Systems Analysis tools developed for Code S needs

TRL 6
State of the Art

- Aerocapture has never been flown in space
- Elements of aerocapture have been flown
  - Aeromaneuvering (lifting, guided and controlled) with low L/D aeroshell, lift vector modulation with low control authority
    - Apollo, Gemini
  - Atmospheric exit human rated for Apollo, but never flown
  - Russian Zond 6 spacecraft performed loft on Lunar return, to reach U.S.S.R. in 1968 (using pre-programmed bank commands)
  - Aeroassist demonstrated spacecraft with similar characteristics
    - Viking – lifting, controlled, unguided Mars Entry, Descent and Landing
  - Ballistic entries completed at
    - Mars, Jupiter, Venus, Earth, Titan (Huygens Jan 05)
    - Shuttle
- Trailing ballute never flown
- Russians built, launched, attempted re-entry of inflatable ballistic attached ballute
Figure of Merit (FOM) Definitions

- Lift-to-Drag Ratio (L/D) - an aerodynamic term which quantifies the relative amounts force, perpendicular to the relative wind that constitutes an upward force (lift), and parallel and opposite the direction of motion (drag). In practical terms, this is a measure of the controllability of a vehicle. A ballistic vehicle has a lift-to-drag ratio of zero; a slender, winged vehicle has an L/D of greater than 1. For aerocapture, a vehicle with a higher L/D can maneuver through a more narrow flight corridor and compensate for greater uncertainties, but will be aerodynamically more complex than the high-heritage blunt body.
IV. Formation Flying Technology

Session Facilitator:
Jesse A. Leitner
Outline

- Executive Summary
- Formation Flying Capabilities to be Validated by ST-9
- Overview and Introduction
  - What is Formation Flying?
  - Scope of the ST-9 Formation Flying Technology Capabilities Area
- Science Mission Capabilities Roadmap and Timeline
- Technology Capabilities Roadmap
- Figure Of Merit (FOM) Definitions
- State Of The Art
- Acronym List
Executive Summary

- **Workshop Addresses Following Technology Areas**
  - "Precision Formation Flying" (PFF): The frequency and tightness of formation control (not just navigation)
  - Continuous process of maintaining or tracking a desired geometric configuration

- **Sessions Topics**
  - Future space science mission needs
  - Desired workshop products
  - Technology splinter session discussions
  - Needs/potential capabilities assessments

- **Splinter Session Topics**
  - Relative Navigation, Relative Attitude, and metrology sensors and algorithms: the engineering measurements of formation flying
  - Formation Control algorithms and actuators: the logic and actuation hardware to calculate and produce forces needed for formation flying
  - Intersatellite Communications, timing, time transfer: systems to share data between the spacecraft, synchronize spacecraft, and disseminate commands
  - Modeling, Simulation, and Mission Design Tools: tools and methodologies needed to verify performance on the ground
  - Autonomous Constellation Management and Control: the high level control layer for multi-spacecraft operations

*Formation Flying Technology*
Executive Summary (continued)

- **Key Observations and Recommendations**
  - The big challenge will be to craft a mission concept which is affordable and technology-centered, and has enough elements with sufficiently high performance to truly alleviate the future risks of upcoming strategic Space Science missions.
  - This team must find the right mix of proving relevance, reducing risk, and controlling cost.
  - For example, a scientific or instrument-centered demonstration - i.e., an interferometry or imaging demonstration, while providing the ultimate validation if successful, may have the tendency to break the bank.

- **Recommendations for ST-9 Flight Experiment**
  - Importance of exercising system elements in an integrated manner
  - Demonstrate mature component technologies in an integrated package
  - Allocate virtually all risk into the system-level aspects instead of component-level

Overview and Introduction

• Precision Formation Flying System Technology is critical for a broad range of future NASA Space Science missions
  - TPF (ASO)
  - MAXIM, MAXIM PF (SEU)
  - Stellar Imager (SEC)
  - LF, PI, SPECS, ...

• The "precision" qualifier carves out a somewhat well-defined niche in the formation flying field with the following characteristics
  - Continuous and robust, possibly high bandwidth intersatellite communications
  - On-board relative navigation/bearing at high data rate with high-precision through the communication links
  - Continuous formation control at high bandwidth and high-precision through the communication links
  - Highly-optimized formation/mission design and analysis
  - Integrated hardware-in-the-loop, high-fidelity simulations
  - Autonomous and robust closed-loop on-board control during science gathering
What is Formation Flying?

**Engineering definition:** the tracking or maintenance of a desired separation between/among two or more spacecraft

**Science definition:** the collective use of multiple spacecraft to perform the function of a single, large, virtual instrument

**ST-9**
you are here

Precision Formation Flying
Scope of the ST-9 FF TCA

- In the context of ST-9, we will focus on the problem of "Precision formation flying"
  - Precision, in this case, refers to a continuous process of maintaining or tracking a desired geometric configuration
  - Collectively, it is the frequency and tightness of formation control (not just navigation)
- Since the focus is on demonstrating technologies critical to future NASA Space Science Enterprise missions, the orbits of primary interest: are HEO, libration points, heliocentric, deep space
Science Mission Capability Requirements
Roadmap and Timeline

- Magnetospheric

- MMS

- Formation Flying Technology

2009 2015 2017 2020 2025
Technology Capability Requirements Roadmap*

- **Autonomous operations**
  - 2009: 5 s/c
  - 2017: 8 s/c
  - 2025: 30 s/c

- **Intersatellite Comm**
  - 2009: 100 kbps
  - 2017: 1 Mbps

- **S/C Formation Control**
  - 2009: 100m
  - 2017: 2 cm
  - 2020: 10 μm
  - 2025: 3 nm

- **Rel Position Estimation**
  - 2009: 10m
  - 2017: 10 cm
  - 2020: 3 nm
  - 2025: 0.5 nm

*some requirements have already been achieved to TRL6 and above at the component level
Figure Of Merit (FOM) Definitions

- Relative position estimate: the estimated value of relative position between spacecraft
- S/C Formation Control: the controlled separation between selected references points between two spacecraft.
- Intersatellite communications bandwidth: the number of bits of data passed from one spacecraft to another.
- Formation geometric dimension: the number of dimensions in free-space spanned by the desired formation
- Spacecraft-to-spacecraft relative bearing: the angel composed of a combination of relative attitude and 3-dimensional position vector between spacecraft indicating the ability to maintain two spacecraft in a desired relative formation in six degrees of freedom.
State Of The Art

- Relative position estimate:
  - 1 micron range change, (relative, not absolute, range between spacecraft) GRACE in low-Earth orbit
  - 2 cm ranging, post-processed (absolute range between spacecraft), determined from spacecraft in LEO to GPS transmitter over 20,000 km distance
- Formation control: kms (EO-1/LS-7)
- Intersatellite comm data rate: 300 Mbps (large EIRP) TDRSS
- Formation geometric dimension: 1 (rendezvous docking)
- Number of s/c managed collectively: ~50 (from the ground)
